There is one more topic to which it might be appropriate to allude on such an occasion as this, and that is the manner of conducting our annual meetings. In former years one day was considered sufficient to accomplish all the work the society had to do; but since 1866 a second has been added. It is a frequent criticism that annual gatherings of medical men rarely accomplish any really useful scientific work, being chiefly of a social character. So far as the strictly literary work of the meetings is concerned this is frequently true, but the metropolis at which the gatherings are held becomes for the time being a medical exhibition on a large scale. The hospitals, schools, and museums, and medical institutions of all kinds, are prepared for the occasion. New inventions, new methods of management, groups of interesting cases, are shown in this way, and any new surgical operation or scientific discovery can thus be brought publicly before the profession. At the last two meetings an innovation has been introduced in the shape of an exhibition of drugs, instruments, and medical books in a room adjacent to the hall of the meeting. As a convenience to visiting members this has proved satisfactory; but a more interesting form of exhibit would be a collection of all apparatus and inventions devised by members of the society. The success of the historical collection of instruments and books this year will, I think, be sufficiently great to suggest a continuance of exhibitions in which members participate. That portion of the meeting which needs life infused into it, and into which at this centennial period it would be most appropriate to introduce a new order of things, is the literary work of the society on the first day. Many excellent papers are annually read, but little encouragement is given to the readers to repeat the experiment. Such an exercise without an accompanying debate is a meaningless, and I might venture to add almost useless, performance. The meeting is thinly attended, and the exercises languish. Such was the condition of most society meetings in this neighborhood a few years since, but a new spirit has been infused into our Boston societies, which it is to be hoped has not been made at the expense of the parent society. The secret of success lies in the care with which the work of the meeting is cut out beforehand. Nothing should be left to chance, with all its terrible possibilities; but a debate, participated in by men whom all are anxious to hear, should be organized early in the season, giving ample time for preparations. Important questions of the day might get the benefit of careful study from our best men, and we might aspire to produce in this way some original work.

The formation of the *Medico-Legal Society*, which has proved so valuable an adjunct to our annual meetings, shows how useful a body an organization designed for special work may become. As the wants of any special department of medicine became urgent in the State, similar societies might be formed, which might or might not be sections of the *Massachusetts Medical Society*.

The educational section has already been alluded to, and would come next in order. Some such plan of gradual development would be preferable to assigning an work to special sections, which, so far as I am aware, State societies have not yet attempted. Departments, which might be contemplated in the near future, are the *Department of Therapeutics*, and of one of the *Departments of Medicine*, which have commenced in the report.

would embrace those branches of State medicine which relate to insanity and to hygiene, bodies which medical officials in the State would naturally turn to for advice or support, and from which, did they exist to-day, work of great value to the State might emanate.

I have thus attempted to sketch the plan of organization of our society from its beginning, and to offer a few suggestions for work in the future. When we compare it with some of the representative bodies of the world, the results of a century's growth are certainly gratifying. In pausing at the first great halting place, to look back through one hundred years, the eye sweeps over a period of unbroken prosperity, unmarred by disputes or factions. In spite of the various waves of delusion or pseudo-science which have passed over the community during that period, the society has maintained an unbroken front, and has always rallied round the flag of truth and integrity. Its attitude has been the only one which a truly scientific body could take. It has been the champion of perfect liberty of action to all, but has withheld the hand of fellowship from those who would deny this boon to others, or would seek to enchain science with the manacles of theory or deceit.

The veterans to whom much of this credit is due are passing away, and younger heads and hands are coming forward. In behalf of the latter, I would say that we assume the trust with a full sense of its responsibility, encouraged by the hope that the century which now opens before us may be as full of harmony and prosperity for our society as the one which has passed away.

A CASE OF HYSTERO-NEUROSIS.

BY GEORGE H. BIXBY, M. D., BOSTON.

Miss W., aged nineteen, native of Massachusetts, of an unusually amiable disposition, in whose family history there were no traces of hereditary disease, first menstruated at fourteen. The function continued normal for a few months, then, without any apparent cause, ceased to appear. Soon after this event she began to suffer from general malaise, fullness and pain about the head. These symptoms were attributed by an irregular practitioner to nasal catarrh, for the treatment of which severe measures were resorted to.

These failing to afford relief, further torture was abandoned, and a course of iron prescribed.

The beneficial effects of the latter were soon apparent by a return of the menses, which had been absent two and a half years.

The function, however, was far from the normal type, and was attended with marked nervous manifestations a few days prior to their appearance, and with a profuse leucorrhoea in the intervals. Dragging sensations about the back and loins and obstinate constipation were now the more prominent symptoms. Six months later a regularly educated female physician discovered retroversion, erosion of the cervix, leucorrhoea, with marked nervous manifestations. Local and general treatment was advised and pursued for two years without permanent relief.

Soon after this I saw the patient at her home. She dated the commencement of her illness as far back as her ninth year. As with all these cases of chronic invalidism so common in our New England towns, she had been an object of pity from the entire community, who, by their well-intended but misguided attentions,

had contributed much toward sustaining and confirming her disease.

I found her reclining, a position she rarely changed. Locomotion was apparently, and certainly in her opinion, quite impossible; a single step was seldom or reluctantly taken without the aid of one or two persons. If she exerted herself to the extent of sitting erect, the feet were instantly placed on a level with the pelvis. The full ruddy cheeks, the peculiar motions of the respiratory muscles, the tone of voice, and manner of speech all went to form a typical picture of hysteria.

She complained of pain in the top of the head and lower part of the back; menstruation recurred every three weeks, always anticipated by more or less nervousness, and attended with pain and with leucorrhœa in the interval. Palpation showed ultimate nutrition below the average, the muscles flabby and apparently atrophied, a large pendulous abdomen, sensitive points on pressure over the cervical and sacral portions of the spine, mammae and external genital organs normal. Vaginal exploration revealed the uterus freely movable, retroverted, its cavity three inches, and sensitive at the fundus. Diagnosis: Chronic endometritis, of which too frequent menstruation, dysmenorrhœa, retroversion, were the physical or direct symptoms, and pain in the head, faulty nutrition, and hysteria were the reflex or indirect symptoms.

The following course of treatment was suggested to the attending physician: on the fourth day after the cessation of the menses the application of the tincture of iodine to the fundus; tenth day or middle of the month, a stronger application, as the tincture of iodine comp., or the acide nitrate of mercury; later in the month a milder application. On account of the shortness of the menstrual intervals, not more than three applications should be made to the fundus in the month; at each treatment of the uterine cavity the patient should remain in bed at least twenty-four hours. At the first sign of chill, fever, or pain following an application, a flaxseed poultice with laudanum should be applied to the abdomen, with rectal suppositories of morphia and belladonna. (Morphia *sulp.* gr. ss., ext. belladonna gr. $\frac{1}{4}$.) As the last application in the month would be a mild one, the use of a retroversion pessary, the instrument to be worn during menstruation and until the next application; also an external supporter; painting the sensitive points of the spine with the tincture of iodine; insuring daily dejection by means of laxatives or enema.

The above course to be carried out with unfailing regularity from October 1st to July 1st; the summer months to be devoted to rest, change of scene and air. Since the patient resided at the sea-shore, the country air was insisted upon.

My suggestions were followed to the letter, as far as practicable, for over three years. Much to my regret she was unable to have a change of climate. The results obtained by this long course of treatment were disappointing in some respects, yet gratifying in others, as evidenced by an examination instituted January 5, 1878.

She was still for the most part confined to the bed and lounge; could change her position in her apartments only by means of crutches. The chief physical improvements were normal menstruation, normal position of the uterus, absence of pain in the top of the head and backache, and relief of constipation. In the mental condition there was little, if indeed any, improvement noticeable. The hysterical picture persisted.

This profound effect upon the nervous system I ascribed to the early age of the patient and long duration of the exciting physical cause. It seemed evident that I had now to do with a pure neurosis, a broken-down nervous system, which called for active and extraordinary means for its restoration.

After due deliberation the following departure in treatment was entered upon, namely:—

(1.) Removal from home. (2.) Ignoring the existence of local disease and complete suspension of all treatment thereof. (3.) Continued forced rest in the horizontal position. (4.) Massage. (5.) Electricity. (6.) Forced exercise. (7.) Extra feeding.

January, 1878, she was brought to Boston, admitted at St. Elizabeth's Hospital, and at once placed in bed.

January 15th, at the middle of the catamenial period, with the assistance of Dr. S. G. Webber, of Boston, a thorough examination was commenced by myself, and concluded by Dr. Webber. We agreed in regard to the general neurotic nature of the case, excluded organic spinal disease, and by means of a battery detected decided evidence of paralysis of the tibialis anticus and a number of fibres of the trapezius muscles of the left side.

The first two steps in the proposed new departure having been taken, namely, the removal from home and rest in bed, Dr. Douglas Graham, of Boston, kindly initiated the fourth step by a thorough application of massage.

January 17th, second day. The experience of the previous evening was followed by a sense of weariness, which, however, did not prevent a comfortable night's rest.

January 18th, third day. I applied, with varying intensity, the second current of electricity to the general muscular system and to the palsied muscles the first current.

January 19th, fourth day. The patient passed a good night; there was less weariness than after massage. At four p. m. I applied massage myself, the joints and muscles being vigorously and repeatedly manipulated for thirty minutes. One quart of milk daily added to the regular full diet list. Milk to be night and day within her reach. Rest continued.

January 20th, fifth day. Passed an excellent night. At four p. m. electricity applied as before. Ordered elixir of iron, quinine, and strychnia, one half drachm, after meals. Diet and rest continued.

The sameness of the treatment would render a daily report monotonous; therefore the progress henceforth will be noted weekly.

January 31st, fifteenth day. Menstruation appeared. All treatment suspended. Medicine, diet, and rest continued.

February 8th, twenty-first day. Two days after cessation of normal menstruation massage resumed. quantity of milk increased to two quarts per diem. medicine and rest continued.

February 9th, twenty-second day. Electricity resumed. Medicine, diet, and rest continued.

February 17th, thirtieth day. Massage and electricity have been applied on alternate days without a single omission.

February 25th, thirty-eighth day. Massage and electricity have been applied as usual. Medicine increased to one drachm three times daily. Medicine, diet, and rest continued. The patient sleeps well, has excellent appetite and digestion.

February 28th, forty-first day. Massage and electricity up to date. Menses appeared. Medicine, diet, and rest continued.

March 7th, forty-ninth day. Two days after normal menstruation. Massage and electricity resumed. Medicine, diet, and rest continued.

March 15th, fifty-seventh day. Massage and electricity as usual, without a single omission. Quantity of milk increased to three quarts in the twenty-four hours. Digestion remains undisturbed.

March 23d, sixty-third day. Massage and electricity. Medicine, diet, and rest continued.

March 28th, sixty-eighth day. The menses appeared. Treatment suspended. Medicine, diet, and rest continued.

April 6th, seventy-fifth day. The condition of the patient indicating it: the treatment was now slightly modified in a manner which I shall call "partial rest" or "bed gymnastics." This consisted in the patient's vigorously and rapidly flexing and extending her limbs while reclining; the exercise to last ten minutes at first, to be gradually increased.

April 14th, eighty-third day. The massage and electricity, which had been continued hitherto without a single omission, were permanently suspended, and the sixth step in the treatment, namely, forced exercise, was substituted.

April 23d, ninety-first day. The last eight days, in addition to gymnastics morning and evening, she has been compelled to rise and dress herself with as little assistance as possible, and to take a few steps about the apartment with the aid of the nurse.

April 26th, ninety-sixth day. Exercise in and out of bed has been continued, and each day a little increased. Medicine, diet, and rest continued.

April 30th, one hundred and fifth day. Menses appeared. All exercise suspended. Medicine and diet continued, and full rest in bed enjoined.

May 7th, one hundred and thirteenth day. Two days after cessation of the catamenia, regular exercise in and out of bed resumed.

May 15th, one hundred and twenty-first day. The orders have been scrupulously carried out, and the patient now walks about the ward without assistance, and with increasing confidence in herself. Appetite excellent, and sleeps well.

May 23d, one hundred and twenty-eighth day. During the past week she has ventured down one flight of stairs, unassisted; sits up without discomfort nearly half a day, and always without resting her feet on a level with the pelvis. Moral condition much improved; seems anxious to further all means prescribed for her relief.

May 28th, one hundred and thirty-second day. The menses appeared. Diet, medicine, and rest in bed continued.

June 1th, one hundred and thirty-eighth day. Two days after normal catamenia, all exercises resumed and slightly increased.

June 11th, one hundred and forty-fifth day. The past week all exercises have been continued and increased. She has descended two flights of stairs and ten steps, attended but unassisted walked the distance of one block; sits up nearly all day, with occasional rests.

June 18th, one hundred and fifty-second day. Exercises have all been continued regularly and gradually increased. On examination I found a great

improvement in the muscular system generally, the palsied muscles completely restored. Among her daily exercises a morning walk is a part of the programme. She was now left to the care of the attendants, with strict instructions that the treatment should be continued with the same care and regularity as heretofore, as fatigue often induces relapse, — a condition ever to be expected, always to be dreaded, in the course of the treatment of nervous affections.

Fourteen years from the date of her first illness, four years from the time she came under my observation, and six months from her entrance to the hospital, she was discharged cured, having gained fifteen pounds, with every function normal, and capable of walking half a mile. At my parting benediction I impressed upon her that nothing was more essential to the permanency of her recovery than that *cure* of all ills, occupation. I am glad to say that her improvement has been uninterrupted.

Whatever uncertainty there may exist in regard to the seat or cause of hysteria, one point, it seems to me, is indisputably settled; that in chronic cases we have invariably to do with general faulty nutrition.

These patients, so far as I have observed them, have weak hearts. The flabby and atonic condition of the muscles of that organ with difficulty propels the vital fluid to the remote parts of the economy; hence the slow, soft, small, compressible pulse and the never-failing cold surface and extremities, dyspepsia, constipation, etc. It stands to reason that conditions like these, of years' duration, demand more than ordinary means to arouse the dormant powers of nature, even after the original enemy has been captured and destroyed.

My patient was no exception to this rule. Believing that exercise, good food, good air, are essential to a vigorous circulation, healthy nerves, muscles, and organs, and finally to a sound mind and body, I offered these to her.

At first, it will be remembered that, physically unequal even to the initial step, she was obliged to depend wholly upon external sources, her own feeble powers being carefully husbanded until by her newly acquired strength she was able to continue and complete the cure.

iodoform.

Dr. H. Hager claims that it is the iodine liberated in the free nascent state that is the active agent in iodoform; that it can therefore be rendered perfectly odorless only by the addition of something which will form a stable compound with the thus liberated iodine, and which will consequently prevent its own proper therapeutic action. He therefore recommends only to attempt to modify the odor of the iodoform by the use of volatile oils, such as anise and peppermint. Balsam of Peru absorbs the iodine and renders it inactive. — *Pharm. Zeitung*.

POTASSIUM CHLORATE.

Dr. H. Hager agrees with Dr. Th. Husemann that the maximum daily dose of potassium chlorate for infants should not be over 1.25 grammes, or two grammes for children of three years, and eight grammes for adults, as larger doses are liable to prove poisonous. — *Pharm. Centrallb.*

RECENT PROGRESS IN OTOLOGY.

BY J. ORNE GREEN, M. D.

AURAL AFFECTIONS IN THE ACUTE EXANTHEMATATA.

GOTTSTEIN¹ calls attention to the lack of observations on the earlier stages of the aural diseases which accompany the exanthemata, and especially scarlet fever. According to Burckhardt-Merian, of all the cases of ear disease which were referable to the exanthemata but sixteen to eighteen per cent. were seen within six months of their first development, and Gottstein's own statistics are even less favorable for the observation of the acute stages of the disease, and for the determination of the question of how the great destruction, which is seen in such cases, occurs. Wreden, of St. Petersburg, who, from his connection with the large children's hospital of that city, had unusual opportunities for early observations, has reported diphtheritic inflammation of the middle ear as very common in scarlet fever; but his observations have not been confirmed by others, as Gottstein thinks, owing to the ear disease being seen only in its later stages, since the diphtheritic exudation, according to Wreden, only continues for fourteen days, and is followed by suppuration.

As contributions to this subject, Gottstein narrates three cases: one of croupous inflammation of the velum, pharynx, nose, and both middle ears, in the second week of scarlet fever; one of diphtheria of the throat, with diphtheritic inflammation of the left tympanum, in the second week of measles; and one of acute desquamative inflammation of both tympanic membranes, with perforative tympanic inflammation, in the course of measles. In the first case, two days after the appearance of diphtheritic membranes in the pharynx and nose great deafness was noticed, and examination showed diphtheritic deposits over both tympanic membranes, which were already perforated, and the same exudation over the tympanic mucous membrane. From the history, the presence of membranes in the nose, and, later, within the tympanum, Gottstein concludes that the exudative process extended up through the Eustachian tube to the tympanum, and produced the destruction from within outwards.

In the second case, soon after the appearance of diphtheritic membranes on the uvula, palate, and tonsils, great deafness, without pain, was noticed in the left ear, and the deeper meatus was covered with similar membrane. After removal the tympanic membrane was found perforated and the cavity in a state of suppuration, but without any membranous deposit, and Gottstein feels uncertain whether the exudation of the ear was an extension from the pharynx or an independent deposit.

In the third case the deposits in the ears were taken for diphtheritic membranes till the microscope showed that they were composed of epidermal cells, and not of a fibrinous exudation.

In regard to treatment of diphtheria, Gottstein has never seen the diphtheritic process shortened by canterization, and considers that therapeutic efforts should be directed to removal of the exudation and disinfection of the mucous membranes. He recommends prolonged baths in aqua calcis and powdering the diseased surfaces with salicylic acid.

NERVE ATROPHY IN THE FIRST COCHLEAR CONVOLUTION.

A case of great interest to pathological physiology is described by Moos and Steinbrügge.² A man aged sixty-three suffered from disease of the brain, and the clinical diagnosis was hemiplegia lateralis sinistra from a cortical affection of the right central convolution; the autopsy showed carcinoma of the anterior central convolution and carcinoma of the stomach. The patient was extremely deaf, the voice being heard not at all on the right, and at a distance of three metres only on the left, side. Two weeks before death an examination of the ears showed normal appearances, but testing proved that the perception for high tones was entirely lost.

Microscopic examination of the right labyrinth showed the central termination and the trunk of the acoustic nerve generally normal, but containing a few atrophic fibres; further examination of the whole lamina spiralis proved that the nerve fibres in the two upper convolutions were perfectly normal, while those in the first or lower convolution had undergone a very marked quantitative atrophy. The hair cells were similarly affected, the inner ones of the first convolution showing only a finely-granular, molecular, colorless mass; the cells in the second convolution were nearly normal, while those in the third were absolutely so.

The cause of the disease, a nerve atrophy from inactivity or intra-labyrinthine pressure, produced by fixation of the stapes, as argued by the authors, we cannot accept as proven, but the loss of perception for high notes associated with the nerve atrophy of the lower cochlear convolution is a pathologico-histological demonstration of Helmholtz's theory of tone perception, as given in his *Lehre von den Tonempfindungen*, 1862, very unique, and of great interest. Only the conclusions of Helmholtz can be given here; the argument would require too much space, and is well known to the whole scientific world. From the laws of the transmission of vibrations and the study of the structure of the labyrinth, Helmholtz concluded that the cochlea was a stringed instrument, with strings of graduated variable length, the longer corresponding to the low tones and the shorter to the higher tones; and, as from the measurements of Hensen the radial length of the lamina basilaris membranacea increased from below upwards to the cupola of the cochlea, the lower convolution of the cochlea is adapted for the perception of the higher notes.

The functional test in this case, in connection with the pathological condition of the first cochlear convolution, is in full harmony with this theory of Helmholtz.

— During the week ending June 11th there were only 188 deaths in Brooklyn, representing a death-rate of 17.31 to 1000 inhabitants, which is the smallest since June, 1879. It must be borne in mind, however, that in the Brooklyn records of vital statistics no account is taken of the deaths occurring in the public institutions connected with the city, as is the case in New York. One reason, also, why the New York death-rate seems so comparatively high is because the floating population is always so very large, and no account of this is taken in the census enumeration upon which the death-rate as given in the weekly official reports is based.

New Instruments.

A METHOD FOR EVACUATING AND IRRIGATING THE BLADDER AND OTHER PARTS.

BY FRANCIS H. WILLIAMS, M. D.

THE usual means of obtaining a to-and fro current in order to wash from the bladder fragments of a foreign body, such as a calculus, has been by compressing and relaxing an elastic bulb. Instead of an elastic bulb the principle of the siphon may be used. In Figure 1 we have a pail containing water, and provided in this instance with a graduation (H), which may serve to measure the amount of water injected. A rubber tube (A) leads from the pail to a three-way-cock of somewhat novel construction. The higher the pail above the cock the greater the pressure of water; when the reservoir is lowered this is diminished. In this way we may have any desired pressure. As the force re-

quired to distend the bladder of a patient under ether is not great (about 30 to 60 cm., or 1 to 2 feet), it is unnecessary to have the reservoir very high above the patient, and if the tube from the pail to the cock be short it is impossible to raise the pressure high enough to do violence to the bladder by over-distention. We shall see later that there are other reasons why the bladder is not apt to be over-distended while using the apparatus. On the stop-cock, near the first tube (A), is a second tube (D), filled with water, and reaching from the cock to a pail on the floor. This is simply

Fig. 1

Figure 1, a view of the whole apparatus. The artist has made the tubes appear too large. Figures 2 and 3 are on a scale of two-thirds the natural size, the stop-cock being two inches in diameter.

a siphon, and sucks with a strength measured by the vertical distance of the cock above the lower end of the tube. Since the column of water in the siphon below the bladder is longer than the column from the upper reservoir to that organ, it follows that fluid will be drawn more rapidly out of than pumped into the bladder.

On the side of the stop-cock, opposite the two tubes A and D, is a third tube, B, which connects the stop-cock with the catheter and bladder. The shape of the handle, N, Figure 3, indicates the form and direction of the opening in the plug of the stop-cock. When the handle is turned a short distance in one direction the bladder is brought into connection with the upper

pail alone, and water flows into the bladder; when the handle is turned in the other direction the bladder and siphon are joined, communication between the upper pail and the bladder being cut off, and fluid is sucked out of the bladder. When at rest half-way between these two points the cock is closed. Figure 2 shows a

A, to pail; B, to bladder; D, to siphon.

horizontal section through the stop-cock. The inner circle represents the plug of the cock; the fan-shaped, unshaded portion is a plan of the opening cut in the plug. In the drawing it will be seen that the cock is

Fig. 3

closed. If the small end, X, of the opening in the plug be turned upwards to A, A and B are joined; if it be turned to D, D and B are connected. In the first instance fluid flows into the bladder; in the second it is drawn out of it. On the outside of the stop-cock, Figure 3, the small bolt, M, allows the plug to be turned only between the points A and D, Figure 2.

When, however, it is desired to have all three openings connected, the evacuating catheter should first be closed; the bolt is then withdrawn by pressing in the knob V, Figure 3, and the plug may then be turned one half way around in the direction M O P, thus bringing the smaller opening, X, Figure 2, opposite B and the larger end connecting A and D.¹ As the plug is turned back again towards B, the bolt, M, is first pressed in by O, and then springs out into the position shown in Figure 3. The position of the cock in which all three tubes are open is used only once, and for the purpose of driving out the air from the siphon D, Figure 1, and filling it with water when the apparatus is set up. At all other times the motion is simply between A and D. In Figure 1 the stop-cock is shown on a stand, and connected with the catheter by

a rubber tube. In this tube is inserted at C a bit of glass pipe of rather larger bore, and within which is a small tassel made from an inch of silk such as is used in ligating arteries. This swings in the current, and indicates the direction, and to some extent the rapidity, of the flow; also the fragments may be seen in the glass tube as they pass out from the bladder. Between the rubber tube and the end of the catheter the arrangement for allowing free rotation of the catheter and the stop-cock is the same as on Professor Bigelow's evacuator, except that the weight on the end of the catheter is diminished by using one instead of two stop-cocks. The evacuating tubes used, than which nothing can be better, are Professor Bigelow's.

The evacuating apparatus, whether it be a bulb or a three-way-cock, may communicate directly with the evacuating tube, as in Sir Henry Thompson's and Ulzmann's evacuators, or indirectly, as shown in Figure 1. Without discussing the obvious advantages of each method, I would suggest, instead of the arrangement in Figure 1, that the three-way-cock be joined directly to the evacuating tube and the intermediate parts be omitted; it would then be well to have a glass tube in A and in D. The stand might be dispensed with.

To use the apparatus, the upper pail is filled with a warm solution of carbolic or boracic acid; the end of the tube A is hooked over the edge of the pail. The tube A, which reaches to the bottom of the pail, is filled by slipping off its lower end from the stop-cock, and sucking with the mouth, so as to draw the liquid over the side of the pail. There is little risk of getting the liquid in the mouth. A is then pinched and replaced on the stop-cock.

This manoeuvre is unnecessary if trouble be taken to have a hole bored in the side of a pail near the bottom and a short bit of brass tube, bent at a right angle, fastened in, over which the rubber tube A may be slipped; with such an arrangement A fills itself when the pail is filled. Supposing A to be full of water, D is filled by stopping the catheter with the thumb, or by closing its stop-cock; then the bolt on the three-way-cock is pressed in and the cock turned half-way around, so that all three openings, A, B, and D, are joined. As soon as water begins to flow into the lower pail the cock is turned back to the position where it is closed, as shown in Figures 2 and 3. The apparatus is now ready for use.

Uncouple the evacuating tube from the tube B, pass it into the bladder, which should contain an ounce or two of liquid, connect it with B, and turn the stop-cock, so as to have D communicate with the bladder; the evacuating tube will be filled by water drawn into it from the bladder. The three-way-cock may now be turned so as to admit fluid to the bladder, and afterward so as to draw it out. Sometimes a longer and sometimes a shorter interval between changes in the direction of the current will give the best success, as shown by the number of fragments passing through the glass tube. The tubes are readily flexible, the upper one, A, being more elastic than the others; its walls are so thin that it was found necessary to slip inside of it near the stop-cock a short piece of brass tube, bent at nearly a right angle, to prevent its "kinking" at that point. The diameter of the other tube is decidedly larger than the bore of the largest evacuating tube. The arrangement at the end of the lower tube, which is shown lifted out of the pail in Figure 1, is to catch the fragments. It consists of a cylinder of wire gauze,

¹ In the construction of the stop-cock the holes are bored with the parts in this position.

with a perforated disc of wood forming its upper end, the lower end being open and stiffened by a brass rim. Outside the neck of a small wide-mouthed bottle is stretched a rubber ring; the lower end of the gauze cylinder fits over this, and makes a joint which allows the gauze cap to be put over the bottle tightly and removed easily. The wooden disc is perforated by a short bit of metal tube, to which is attached on one side the rubber tube from the stop-cock, and on the other a short piece of tubing leading into the glass bottle. The fragments and water come into the bottle, but the gauze prevents the former being carried out.

Fig. 1

Figure 1 shows the parts of the three-way-cock separated: on the left the plug of the stop-cock, next to this the shell, and on the right a disc and thumb-screw for holding the plug in place.

Although the apparatus was thought of while watching an operation for litholapaxy, it may be adapted to pumping or washing out any cavity or organ. When tested on a pig's bladder it worked admirably. It would seem that by this method the evacuation of the human bladder could be done quickly and neatly, without the entrance of air and with little risk.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

TYPHUS FEVER IN NEW YORK.

At a stated meeting of the Academy, held May 19th, Professor Edward G. Janeway, one of the commissioners of the New York Board of Health, read a paper on the present outbreak of typhus fever in the city. In commencing he stated that typhus fever had occurred in New York during the last five years to a greater extent than was generally supposed; although it was by no means so common as one might infer from the reports of many of the German practitioners in the city, who, when they meant typhoid fever, frequently wrote *typhus*, and omitted to qualify it by the adjective *abdominalis*. Thus, last autumn an interesting group of cases had been discovered, which he had reported in considerable detail to the County Medical Society. A family of adults, living in the eastern part of the city, were affected with the disease, and the nurse who was

in attendance also contracted it. One of the family died, and the post mortem showed conclusively that the disease was typhus. The first one to be brought down with it was a young woman who was employed in a factory, and on investigation it was learned that a girl who worked with her had also been taken ill at the same time. The latter, it was then ascertained, was the last of a family living in an entirely different part of the city to be sick with a fever which was undoubtedly typhus. It was impossible to trace the origin of the disease further; but the people living in the same house stated that the family were "so filthy in their habits that they ought to have been sick." There was no other typhus in New York at the time (September, 1880).

For some time past typhus had prevailed to some extent in Philadelphia. One case had been reported to the Board of Health in October last, one in November, and several during the months of December, January, February, and March. It was noticeable that in October, November, and December there were an unusually large number of cases of typhoid in Philadelphia, and it seemed altogether probable that in some of these there must have been a mistaken diagnosis, the disease really being typhus. Since early last autumn there had been a continuous series of cases in London, Liverpool, and Dublin, and in some weeks there had been as many as ten deaths from it in the latter city. In other foreign cities also it had prevailed, and in St. Petersburg there were twenty or thirty deaths from it in February. In Camden, New Jersey, there were fifty deaths from typhus between November 15, 1880, and January 17, 1881.

In considering the history of the present outbreak of typhus fever in New York, two facts of importance present themselves. The first is that there were cases of the disease in the city before it made its appearance in the "Shiloh" lodging-house, at the corner of Prince and Marion Streets, and the second that this lodging-house for tramps constituted a favorable *nidus* for the fostering of the fever. In substantiation of the first statement Dr. Janeway mentioned a number of cases which had occurred previously, and stated that he had no doubt that there were still others in which the true diagnosis had been mistaken by the physicians in attendance, since the disease had been so comparatively rare in New York during the past ten years. The outbreak had commenced in March, and thirty, at least, of the cases had been distinctly traced to the lodging-house mentioned. Of the first fifty-six cases reported four deaths had occurred from other causes, and six from the typhus fever. The first post-mortem examination was made on the 19th of March on a patient who died on the 17th at Bellevue Hospital. The whole number of cases and deaths, tabulated according to the ages of the patients, was as follows:—

Under 15 years		8 cases	no deaths.
From 15 to 20 years		17 cases	3 deaths.
" 20 " 25 "		44 "	5 "
" 25 " 30 "		48 "	6 "
" 30 " 35 "		38 "	10 "
" 35 " 40 "		41 "	9 "
" 40 " 45 "		28 "	10 "
" 45 " 50 "		15 "	5 "
" 50 " 55 "		13 "	4 "
" 55 " 60 "		17 "	5 "
" 60 " 65 "		5 "	1 death.
" 65 " 70 "		6 "	3 deaths.
" 70 " 75 "		2 "	2 "
" 75 " 80 "		1 "	1 death.

Making in all 283 cases and 64 deaths. The greatest mortality had occurred among the patients received from Hart's Island, out of eleven cases there being only two recoveries. After the disease had once obtained a lodgment it spread, as a rule, by personal contact, although this could by no means be proved in every instance. In this connection Dr. Janeway mentioned several interesting cases in which the fever had been contracted with a minimum amount of exposure to it. Eight orderlies in the fever hospital had been attacked, and one had died from the disease, but not a single physician had as yet suffered from it, although many of those at the hospital, as well as those in the service of the Board of Health, had been very freely and constantly exposed to it.

Dr. Janeway then went on to speak of the measures which had been adopted by the authorities to prevent the spread of typhus. Unless complete isolation could be secured (which was rare in the class generally attacked by the disease) the patients were removed to the hospital on Blackwell's Island, while the premises which had been occupied by them were disinfected and fumigated with sulphurous acid, and, if it was deemed advisable, ordered to be altogether vacated by the families. The clothing was burned, and in cases where the poverty of the individual rendered this necessary new clothing was furnished by the Board of Health. An extra corps of physicians was appointed for the purpose of visiting and inspecting the various cheap lodging-houses in the city, and insisting that there should be at least three hundred cubic feet of air for each inmate. A most rigid and constant inspection both by night and day was maintained by this corps, and still another corps was appointed for the special purpose of tracing the history of each individual case. On Blackwell's Island the disease was treated in tents, and the patients were fed upon milk and beef tea, and allowed as much stimulus as the circumstances of each case required. When the degree of temperature demanded it cold sponging and the use of Kibber's cot were resorted to.

The matter of cheap lodging-houses Dr. Janeway considered to be one of importance from a sanitary point of view, and there could be no doubt that even when they were well conducted there was in them a source of more or less danger in the way of infectious diseases. Thus the very one which was started with a semi-philanthropic view, the "Shiloh" house, had given the most trouble in the present outbreak of typhus. Such places attracted a large number of tramps and other worthless characters to the city in the winter, and really made New York the cheapest place in which they could live. The allowance of three hundred cubic feet of air for each individual, which was insisted on in the New York lodging-houses, was fifty feet in excess of the requirement of the London poor-law. As to the various hospitals in the city, he thought that every such institution should have an isolated pavilion, containing several rooms, in which every suspicious case of disease could at once be placed. There was a pavilion of this kind attached to the German hospital, and he hoped that before long all the hospitals in New York would be similarly provided.

The president, Dr. Fordyce Barker, after alluding in complimentary terms to the energy which Dr. Janeway, in his capacity as health commissioner, had displayed in dealing with the fever, called upon Professor Flint, who remarked that the facts of the paper touched upon

some very interesting points, especially in regard to aetiology. The first question suggested was, whether typhus fever always required a special cause or germ (either literal or figurative) developed in the body of an individual affected with the disease, or whether this cause was capable of being originated *de novo*. Some years ago he had known of an outbreak of typhus which occurred in an isolated county almshouse that was overcrowded, and whose rooms were small and badly ventilated, and in this instance, at least, it was quite impossible to trace the disease to importation from without. Other similar and equally well authenticated cases were on record; but in no one of them could it be positively asserted that the disease might not possibly have been imported, and the matter must still be regarded, he supposed, as an open question.

Assuming, however, for the time being, that the disease required a germ for its development, it must be granted that we did not know how long this germ might retain its vitality so as to be capable of full activity under favorable circumstances. It might, perhaps, remain long latent, like the kernels of grain buried with an Egyptian mummy.

Another important point brought out by Dr. Janeway's paper was the vast difference in susceptibility to the disease which was found to exist in different individuals; so that it seems to be a fact that certain accessory causes were necessary for its development in addition to the germ itself. Especially did effluvia from human bodies and defective ventilation seem to stand in this relation, and those who believed that typhus was capable of originating *de novo* held that it could be produced by a concentrated effluvia.

In regard to the prevention of the diffusion of the disease the importance of the matter was sufficiently apparent, and he had no doubt that the present outbreak would soon be stamped out by means of the active measures which had been adopted by the Board of Health. In this connection Dr. Flint referred to the suppression of cholera some years ago by the New York Health Board, which he regarded as one of the most brilliant achievements in its history, and also to their more recent triumph in completely stamping out small-pox in the city.

Professor Loomis said that he was especially interested in the paper because it brought vividly to mind his experience with typhus in 1862 and 1863, when he himself was called upon to deal with an epidemic of greater severity than the present outbreak. At Bellevue Hospital as many as fourteen cases of it were sometimes admitted in a single day; the patients being brought from various parts of the city, although the greater part of them came from Baxter Street and the streets and alleys adjoining. In making his investigations concerning the history of the outbreak, he finally ascertained that the outbreak probably originated in the case of a little girl who came out from Ireland to visit an aunt here. The aunt, who lived on the top floor of a rear tenement-house, took the disease and died, and the fever then gradually made its way down through the other floors of the house; after which it spread to the building in front. Some of the families soon became alarmed and went to other habitations, and thus, no doubt, the disease was carried to different parts of the city.

He was not one of those who believed that it was necessary to trace any outbreak of typhus to importation at the time: but he considered it a disease which

was indigenous to certain localities, where it could always be found, while in all other localities it was always imported. The same was true of yellow fever, which we should not expect to originate in New York, although when once introduced it was well known how it could develop there under suitable conditions. The poison of typhus, he believed, was brought to this city more frequently than was generally supposed; but the conditions were not always favorable for its development and spread.

The questions suggested by the paper were: (1.) Is typhus fever a disease of spontaneous origin? (2.) Is it propagated in other ways than by personal contact? (3.) What are the best means for arresting its development and diffusion? The miserable tramps which infested the city in the winter were in every way fitted to bring contagion, and it was always a very difficult matter to find out where they came from. In all large cities it was, indeed, often impossible to trace the origin of epidemics. The case mentioned by Dr. Flint was the strongest one of which he knew in favor of the spontaneous origin of typhus, and yet it by no means afforded certain proof of this. Then, as to the second point in the outbreak of which he had spoken, the clothing of the typhus-fever patients in Bellevue was stored in pigeon-holes, and a certain portion of it was washed; yet, so far as he knew, not a single individual who was engaged in handling these clothes contracted the disease. On the other hand, all those who carried the patients and all the nurses and physicians who were sufficiently exposed were taken with it. In order to contract typhus, he believed that the exposure must, as a rule, be long and intimate; and he thought that the reason why the hospital physicians had escaped in the present outbreak was because the patients were treated in tents, and the ventilation was thus as perfect as possible. In the way of prevention fresh air was the *sine quâ non*, and he knew of nothing which had the same power not only of preventing it, but also of relieving the symptoms after the disease had become developed. In many cases a vast improvement had been noticed in patients immediately after their removal from badly ventilated rooms to tents. In conclusion Dr. Loomis remarked that the disease was always most fatal in those past middle life, and stated that among sixty cases which he had seen in children there was scarcely a death.

Dr. John C. Peters said that he had felt certain that the famine in Ireland last year would be followed by typhus fever, and feared that with the enormous amount of immigration that was taking place the disease would quickly spread to New York; yet there was no history of any such importation in the present outbreak. For his part, he believed in the spontaneous origin of typhus fever from the decomposition of organic matter, and he had never known the city to be in a filthier state than it was last autumn; so that the conditions are altogether favorable for its development here. Typhus fever was a filth disease, and the tramps among whom it spread were more dirty than they would otherwise have been on account of the disgraceful condition of the streets. He had no doubt that it would be stamped out, but at the same time he could not but believe that if we had had a cleaner city the outbreak would have been prevented. He considered that there was now abundant proof that certain diseases like diphtheria and typhus might originate *de novo*, and was convinced that they arose thus spontaneously both in New York and Philadelphia.

Dr. E. H. Janes, assistant sanitary superintendent, explained that the Shiloh lodging-house had not been closed at once on the discovery of typhus there, because it was believed to be safer to keep a constant and thorough supervision over it than to scatter the disease to other localities by driving out the lodgers.

In the course of some concluding remarks Dr. Janeway said that he could not understand why those handling the clothing of typhus-fever patients in the epidemic to which Dr. Loomis had referred had all escaped the disease, for it was certainly contrary to the usual experience in typhus; and Dr. Barker then related two instances in which the infection was conveyed by the clothing alone.

Before adjournment some resolutions similar to those passed by the County Medical Society were adopted, congratulating Spencer Wells (who is an associate Fellow of the Academy) on the completion of one thousand cases of ovariectomy, by means of which the lives of seven hundred and sixty-nine women had been saved; and the president, Dr. Barker, who expected to sail for England on the 21st, was instructed to present the resolutions to Mr. Wells in person.

THE AMERICAN NEUROLOGICAL ASSOCIATION.

THE annual meeting of the Neurological Association was held in the hall of the Academy of Medicine, New York, on Wednesday, Thursday, and Friday, June 15th, 16th, and 17th, with the president, Dr. Roberts Bartholow, of Philadelphia, in the chair. At the first session, Wednesday afternoon, the following papers were read: Tendon Reflex in General Paralysis of the Insane, by Dr. J. C. Shaw, of Brooklyn; The Central Nervous System of Reptiles, by Dr. John J. Mason, of Newport, R. I. (read by the secretary); The Action of an Irritant, by Dr. Isaac Ott, of Pennsylvania; and Peculiar Effects of Bromide of Potassium in Insane Epileptics, by Dr. H. M. Bannister, of Chicago (read by the secretary). At the evening session on Wednesday, Dr. A. D. Rockwell, of New York, read a report of a case of peripheral paralysis resulting from pressure, after which the report of a most remarkable case, designated as one of destructive lesion of the left hemisphere, which had been presented by Dr. H. D. Schmidt, of New Orleans, was read by the secretary. Dr. J. S. Jewell, of Chicago, then read a paper on the Early Use of Strychnia in Myelitis, the title of which he afterwards changed to the following: On the Early and Free Use of Strychnia in Subacute Myelitis and Allied Forms of Disease of the Spinal Cord.

At the Thursday afternoon session the first scientific business was the discussion of Dr. Jewell's paper, after which Dr. W. J. Morton, of New York, read a paper on A New Induced Current of Electricity, a title which was subsequently modified so as to read, The Static Induced Current of Electricity. The following papers were also read at this session: The Hypothetical Auditory Tract, by Dr. Graeme Hammond, of New York; The Medical Use of Static Electricity, by Dr. George M. Beard, of New York; and How to Use the Bromides, also by Dr. Beard. In the evening an elegant reception was given to the Association and their friends by Dr. W. A. Hammond at his residence on Fifty-Fourth Street.

At the session on Friday afternoon the following papers were read: Nerve-Stretching in Progressive Locomotor Ataxia, by Dr. W. A. Hammond; Ciliary Spasm of Central Origin, by Dr. H. Gradle, of Chicago; A Case of Diffuse Myelitis, by Dr. F. T. Miles, of Baltimore; and A New Foot Dynamometer, by Dr. W. R. Birdsall, of New York. Dr. Graeme Hammond also gave a description of a new instrument of similar character which he had devised. At the concluding session, Friday evening, the following papers were presented: Case of Tumor of the Pons, with Specimen, by Dr. F. T. Miles, of Baltimore; Case of Tumor of the Pons, with Conjugate Deviation of the Eyes and Rotation of the Head, by Dr. Charles K. Mills, of Philadelphia; Case of Chorea Major, by Dr. Frank P. Kinnicutt, of New York; Resistance of Tabetic Patients to Aconitia, by Dr. E. C. Seguin, of New York; and a Case of Post-Diphtheritic Paralysis, also by Dr. Seguin. In the latter the diphtheritic trouble was located in the anus, and had ensued upon a slough caused by the use of carbolic acid in the treatment of piles at the hands of an empiric. During the meeting of the Association the following papers were read by title only: Brain of Hydrocephalus from a Dog, by Prof. Burt G. Wilder, of Cornell University, Ithaca, N. Y.; Investigations into the Earlier and Obscure Symptoms of Lead-Poisoning, by Dr. J. J. Putnam, of Boston; On the Function of Nerve-Cells, by Dr. A. B. Clevenger, of Chicago.

The following officers were elected for the ensuing year: president, Dr. W. A. Hammond, of New York; vice-president, Dr. L. C. Gray, of Brooklyn; secretary and treasurer, Dr. E. C. Seguin, of New York; extra members of the council, Dr. J. S. Jewell, of Chicago, and Dr. Isaac Ott, of Pennsylvania. The following new active members were elected: Drs. H. Gradle and A. B. Clevenger, of Chicago, Drs. Charles K. Mills and Wharton Sinkler, of Philadelphia, and Prof. Burt G. Wilder, of Cornell University. Up to the present time there had been no provision in the constitution or by-laws for the creation of honorary members of the Association, but during this meeting amendments were made which permitted the appointment of both honorary and associate members, and the following gentlemen were elected to these positions: Honorary members, J. M. Charcot, of Paris; J. Hughlings Jackson, of London; W. Erb, of Leipsic; C. Westphal, of Berlin; and Theodore Meynert, of Vienna. Associate members: Thomas Stretch Dowse, of London; W. R. Gowers, of London; David Ferrier, of London; H. C. Bastian, of London; J. Russell Reynolds, of London; Moritz Bernhardt, of Berlin; Camillo Golgi, of Reggio, Italy; and Dr. Obersteimer, of Vienna. Dr. N. B. Emerson and Dr. Lombard, who had formerly been active members, were also constituted associate members, the one having moved to Honolulu, Sandwich Islands, and the other to London. The Association adjourned to meet in New York, as usual, on the third Wednesday in June, 1882.

— At a stated meeting of the New York Academy of Medicine, held June 2d, the papers of the evening were as follows: (1.) The Use and Value of Artificially Digested Food, Peptone, by Dr. George B. Fowler. (2.) Photo-Micrography and its Application to Histology (illustrated), by Prof. J. W. S. Arnold.

Recent Literature.

The Sanitary Care and Treatment of Children and their Diseases. Boston: Houghton, Mifflin & Co. The Riverside Press, Cambridge. 1884.

This book is made up of a series of five essays, by Drs. Elizabeth Garrett-Anderson, Samuel C. Busey, A. Jacobi, J. Forsyth Meigs, and J. Lewis Smith, prepared by request of the trustees of the "Thomas Wilson Sanitarium" of Baltimore, Md. For the establishment of this sanitarium, the late Thomas Wilson, of Baltimore, bequeathed the munificent gift of five hundred thousand dollars, "for the purpose of securing a summer retreat for sick children from the heat and unhealthfulness of the city, and for such other kindred purposes as may be hereafter determined upon by the corporation." The trustees appointed by the testator for carrying out the provisions of the above trust decided, preliminary to the formation of any definite plan of procedure, as they tell us in their circular, "to correspond with a few persons at home and abroad who are eminent for their experience and success in the treatment and care of sick children, and to obtain essays from them, to be published for the benefit of this and similar institutions."

In these essays are considered, at the request of the trustees: "The best method of establishing a summer retreat for sick children under the most favorable hygienic and local conditions; the regulations suitable for receiving and administering medically and otherwise to those who shall be the proper objects of their care; the character of the buildings that may be requisite; how best to provide for mothers or nurses accompanying their children; and generally such incidental recommendations as experience or reflection may commend as valuable and useful." Suggestions were also asked for in reference to the most practicable means of lessening the risks and dangers incident to children exposed to the heated and impure atmosphere of a large city during the summer months; also as to the best methods of extending a general knowledge of simple hygienic rules for the treatment of children at home among the poorer classes.

The field of inquiry, it is thus seen, has been a wide one, and includes all practical points involved in the management of children. The high and scientific character of the authors of these five essays is a sufficient guarantee that the work has been well and thoroughly done; and it will subserve the double purpose of being a valuable work of reference for those who may be engaged in carrying out similar trusts, and at the same time most interesting and instructive reading for all concerned in the care and welfare of little children. The essays of Drs. J. Forsyth Meigs, and J. Lewis Smith should be read by all practitioners engaged in the treatment of children, dealing largely, as they do, with infant diet in health and disease, and with much detail.

The book is a credit to the publishers, and would make a handsome ornament to any parlor table.

TINCTURE FERRI CHLORIDI.

Dr. H. Hager recommends that tincture ferri chloridi be mixed with simple syrup and then with milk; this mixture not affecting the teeth, nor the usual stypitic taste being apparent. — *Druggists' Circular*.

Medical and Surgical Journal.

THURSDAY, JUNE 30, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,

No. 1 PARK STREET, BOSTON, MASS.

ATHLETICS AND TRAINING.

Just at this season of the year, in this country, athletic competitive exercises are most pursued and attract the most attention, and this is especially true of those in which young and enthusiastic amateurs take part. During the last weeks of June or the first weeks of July the various friendly contests between the different college and university crews, nines and elevens, occur; and to these have been added of late years running races, which also tax the heart and lungs. The results of the previous months' judicious or injudicious training and practice are put to the test of a struggle, more or less short, sharp, and severe. Many of the contestants are benefited by the process; some do themselves at least no harm; whilst a few, undoubtedly, are temporarily or permanently injured. This must sometimes be the case in a close rowing race, for instance, over a four-mile course, in which the least fit man fails to do his part toward sustaining the honor of his college unless he utterly "pumps himself out," or in which the best man finds himself suddenly called upon to do his own work and that of a disabled comrade beside. These are not moments when results and relative values are viewed through the spectacles of the calm and cold psychologist, and efforts are sometimes made in haste which have to be repented of at leisure. At the age of the average college athlete, even at a period when to sneer is more cultivated than to cheer, ambition and vanity predominate over prudence and discretion. The dangers of overtraining, and of shirking training and still attempting to do the expected work, are also real; moreover, although the training of the amateur athlete is more correct and sensible than it was ten or fifteen years since, it is still not uncommon that the best intentions merely emphasize the worst methods, at least for the individual. This must occur unless it is constantly borne in mind that it is the individual and not a class which is to be considered, and unless the regulation of training and the selection of candidates are controlled by some one with an education, as well as practical experience, which will enable him to estimate all the factors involved in the equation.

We took occasion to touch on the question of athletics in our brief editorial remarks, under the head of Physical Exercise and Human Endurance, last September, and will have something more to say on the physiology of training and of athletic competition in a future number. Macdon touches important points on pages 16 and 17 of his book on training when he

says, "In fact, a boat race has now become a matter of wind rather than of muscle, and, as an old water-man at one of our races, last year, remarked, in my hearing, 'the crew that can bucket it the fastest will win the race, if they don't bust.'" Again, "The best men fall off when the racing or the exclusive training exercise for the racing begins; under it a powerful man dwindles."

The question is to find out just how near the "busting" and the "dwindling" point the individual dare venture for the final contest. Some of the ware necessarily gets spoiled in the firing, and the amount is likely to be proportioned to the skilled intelligence of the person in charge.

SKODA, ROLLESTON, LITTRÉ.

In the deaths of Prof. Josef Skoda, of Vienna, and of Professor Rolleston, of Oxford, their respective universities have lost distinguished ornaments, and medicine and medical science investigators not easily replaced. In Skoda not a few of our readers lose a former much-valued teacher. Dr. Skoda was seventy-six years of age; Professor Rolleston but a little over fifty. The latter was elected an honorary member of the Massachusetts Medical Society at its last meeting.

M. Littré, although best known as a lexicographer and philologist, studied medicine in the school and hospitals of Paris, and at one time looked to its practice as his future career. His edition of the works of Hippocrates with a French translation and his Dictionary of Medicine have the stamp of honest, thorough work, which marks all he did, and that was an immense amount. He was an indefatigable worker, which, though he lived to be eighty years of age, his dictionary of the French language alone would attest. His famous contest with Bishop Dupanloup for admission to the French Academy will be recalled by many of our readers. His election was for some time prevented by the bishop, but when M. Littré was finally admitted, in spite of this persistent opposition, — had their places been reversed it would have been termed *persecution*, — the bishop withdrew from the Academy, and never attended another meeting.

MEDICAL NOTES.

— Three cases of small-pox, the origin of which could not be traced, were brought to the notice of the Boston Board of Health during the past week.

— We are sorry to notice that in our report last week of the after-dinner speeches of the centenary celebration some of the chairman's toasts were improperly included in quotation marks. Our report does not claim to be an exact reproduction of all that was said, but is as near an approximation as a skillful stenographer could produce. We are conscious that unavoidable haste has done injustice to some of the toasts and speeches. The eventual publication of the proceedings by the society will probably give the most accurate report.

—The city council of Dover, N. H., becoming alarmed at the frequent occurrence of small-pox throughout New England, at its meeting in the first week of June, passed resolutions appointing a physician in each ward of the city, whose duty it should be to visit every dwelling-house, hotel, workshop, and store, and vaccinate, at the expense of the city, with kine virus, each person who needed it. It was decided by the physicians named in the resolutions to recommend that every person who had not been vaccinated during the last seven years (unless protected by variola) be vaccinated. The work was commenced on the 11th inst., and is about completed. Some thirty-three hundred people, out of a population of twelve thousand, have been vaccinated, making the most thorough work of its kind for many years.

—The following is reproduced by the *Medical Times and Gazette*: Professor Depaul, giving an account to his class of the magnificent obstetrical clinic (constructed at the moderate cost of twelve thousand francs per bed), and stating that an amphitheatre had been provided in which remarks might be made that it would not be proper to make at the bed-side, observed that it reminded him of some words which, to his infinite regret, had once escaped him when examining a poor woman, who, to all appearance, had succumbed to a uterine hemorrhage. Turning to the persons who surrounded him he said, "This woman is dead." But to his great stupefaction the patient replied, in a feeble voice, "*Pas encore!*" So little dead, indeed, was the poor woman, in spite of all appearances, that in three weeks she left the clinic perfectly well. This "*pas encore*" corresponds pretty well to what occurred to Récamier one day when he was called by a colleague to see a man, the subject of typhoid fever. Récamier complained of having been called to the case too late, saying that the patient apparently could not survive the night. The latter, on hearing him, emitted a certain noise from the lower passages, accompanying it with the words, "*Qui crepita vit!*" And in fact, not only did he not die of the typhoid fever, but he is alive at the present time. — *Gaz. des Hôpitaux*.

NEW YORK.

—Commencing with the July number, the *New York Medical Journal* is in the future to be devoted more particularly, though not exclusively, to obstetrics and gynecology, and an addition will be made to its present title which will indicate this new departure.

— "Dr. Romaine, from Paris, the king of dentists," who for some time past has been making a sensation in the streets, has lately come to grief, having been arrested and fined the other day for collecting a crowd and blocking the public way. This is a mountebank who has been in the habit of riding about the city, dressed like a circus performer, in gaudy colors and tinsel, in a four-horse open carriage, having a huge placard with the above inscription, and preceded by another, which was drawn also by four horses, and containing a brass band of six or eight pieces. At certain intervals this magnificent *cortège*

would come to a halt, and the king of dentists, from his seat in the barouche, would begin pulling the teeth of any individuals who might desire to have the operation performed, and "all for the sake of charity," as he announced. In the mean while an immense crowd would be attracted by so novel a spectacle, and an assistant of the illustrious personage would then commence disposing of certain bottles of patent medicine, which were eagerly bought up by the wonder-stricken assemblage. "Dr. Romaine" seems to have been doing a thriving business, notwithstanding the fact that (as he incidentally remarked to a newspaper reporter) his sole purpose in the world is to be charitable, for he nonchalantly paid the fines that had been imposed upon him and his attendant medicine-vender from a one-hundred-dollar bill, and as he drove off in his carriage from the Yorkville Police Court, where he had been arraigned, threw a handful of change among the crowd waiting outside, who gave him a most enthusiastic reception when he reappeared. The truth of a statement of his, however, to the effect that he had been offered ten thousand dollars by the dentists of Brooklyn to leave that city, where he had been "practicing" before he came to New York, may be open to some question.

—Dr. Beard has been making some experiments in "transvoyance," in the person of a Mrs. Carpenter, the wife of a popular lecturer on mesmerism, which have attracted considerable attention, and which, to say the least, are certainly very curious. Hearing that this lady was a subject of extraordinary susceptibility, who, while in trance, had the power of seeing objects around her when she was blindfolded, he obtained permission to apply any tests that he might desire in her case. When she had been put in a trance state by her husband, who was not permitted to come within twenty feet of her afterwards, Dr. Beard and a medical friend of his, who was a surgeon, bandaged her eyes with all the skill that they could devise, first using cotton-batting and then three bandages of cotton cloth. When this was completed, Dr. Beard drew from his pocket a pack of cards, and held them, one after another, to her forehead in such a manner that neither he himself nor any one else in the room could see their faces, yet in almost every case she told the card at once, hesitating only between the nine and ten spot cards. He then held some large type print to her forehead, and this he found she could read slowly, though she failed to decipher fine print. On coming out of the trance Mrs. Carpenter could remember nothing that had taken place. On a subsequent occasion the same experiments were repeated, but failed completely, a result which the subject attributed to the wet weather which then prevailed, saying that she had found that this was always unfavorable to trance experimenting in her case. The third time the tests were applied, however, the same success was met with as at first. Dr. Beard states that he exhausted every means of preventing deception which occurred to him or his friends, and he is convinced that it could not possibly have been practiced.

—The City Board of Health has asked the board of estimate and apportion to appropriate the sum of thirty thousand dollars for the salaries of inspectors, physicians, and nurses to be appointed during the next six months to aid in the suppression of contagious diseases.

—Prof. T. Gaillard Thomas having resigned his position in the College of Physicians and Surgeons on account of the pressure of private work, Dr. Paul F. Mundé, editor of the *American Journal of Obstetrics*, has been appointed lecturer on gynecology in that institution. Dr. Mundé is at present one of the assistant surgeons to the Woman's Hospital, and professor of diseases of women in the medical department of Dartmouth College.

CHICAGO.

—The Tenement-House Inspectors of Chicago have recently reported over fifty houses in a bad sanitary condition, many of the buildings being overcrowded and impregnated with sewer-gas from untrapped and leaky plumbing, and others in a rickety condition, filthy, and unfit for habitation. Of 220 houses, containing 2741 rooms, examined by the inspectors, containing 757 families, aggregating 3471 persons, 54 were served with notices, 54 nuisances were abated, 63 rooms whitewashed, 35 vaults and catch-basins cleaned, 13 defective drains repaired, and 8 filthy premises cleaned. There were 1609 houses reported on in writing and inspected in nine weeks. According to newspaper accounts, small-pox seems to be firmly established in Chicago, the Poles, Bohemians, and Germans being the most subject to the disease.

Miscellany.

THE RELATIONS OF THE MARINE HOSPITAL SERVICE TO COMMERCE, THE PUBLIC, AND THE MEDICAL PROFESSION.

MR. EDITOR. — I have had sent me what purports to be an official publication of the Medical Society of the State of California, which to appearance presents for discussion by the society *The Relations of the Marine Hospital Service of the United States to Commerce, the Public, and the Medical Profession*; but which, by open charges, and that more dangerous because more insidious style of attack, by cunning implications and innuendoes, arraigns that important government service, without opportunity for defense, before a tribunal which has no jurisdiction or interest in the matter. What step, except to refer it to the committee on legislation, the California society took in the matter I do not know. Action which would condemn without trial, and without a full knowledge of facts, is inconsistent with the discretion and sound judgment of fair-minded men; and such a course, I am confident, would not be likely to govern our brethren on the Pacific coast.

The report on the Marine Hospital Service is at once ill-judged and ill-timed; it bears an ill animus throughout; it is founded on perverted statements, and puts together, as bearing on each other, facts which have no proper correlation. I purpose to take up and answer some portions of this singular production.

The author of the report states that the natural inference is that "a government hospital is kept for those in the service of the government, such as United States marines; while the fact is that our marine hospitals are kept by the government for those not in its service, employees of individuals and corporations." Except that the Service cares for the officers and men of the Revenue Marine Service, who by the Regulations are required to pay Marine Hospital dues, and, upon proper application, for those of the United States Navy and those engaged in vessels of the Coast Survey and Light-House Board, this is strictly true. The author, however, fails to note in the same connection that marine hospitals are not, in the true sense, *government* hospitals, as are those belonging to the war and navy departments; that, although the buildings and grounds belong to the government proper, the Service is maintained by a private fund, accumulated from monthly dues *paid by seamen of the mercantile marine* while in health, for their own use, as a means of insuring proper care during sickness; and that the government is merely the trustee of this fund, and authorized to employ it, under strict regulations, only for legitimate purposes. As a matter intimately connected with our shipping, and vital to its integrity, the care of the merchant seaman becomes a national concern and worthy the nation's care.

"Recently published reports of the Service estimate the number of such persons cared for in its marine hospitals at 170,000, a number greater than our army and navy combined." The author of the report made a perfectly true statement, but left a wrong impression; he should have said "a clientele of 170,000, of which about twelve per cent. [omitting readmissions, etc.] become patients every year." He might also have said, in favor of the Service and in testimony of the work it is doing, — but without depreciation of the medical men of the army and navy, — that, while the army with 25,000 men has a medical staff of about 200, not including contract surgeons, and the navy with 8000 a staff of *about* 100, the Marine Hospital Service cares for its 170,000, with 25,000 actual patients in each year, with but thirty-five medical officers and as many active assistant surgeons.

"Your committee find that the crippled and infirm or permanently disabled are not provided for by this Service." Granted! Neither are they in any of the *hospitals* of the land. It is a fortunate circumstance, however, that several of our States have snug harbors and similar institutions in which our worthy and tempest-tossed seamen can be well cared for in their declining years. It is noticeable, also, that no mention is made in the report (bearing date April 21, 1881) of the fact that the Surgeon-General, in his last two published reports for 1879 and 1880, has urged the establishment of a national snug harbor, under the care of the government, to meet this very end. In closing his remarks on this subject, in the report for 1879, the Surgeon-General says, "Soldiers and naval seamen have for many years been provided by law with a permanent home when worn out in the service or disabled by casualty, and a similar provision for the seamen of the Mercantile Marine would tend greatly to improve the character of American seamen."

The author states that "the marine hospital system furnishes relief at designated seaports and river stations inland, and *only at such points*," and follows up his statement with a quotation from the Regulations, which would be very effective in corroboration of his state-

ment, but, unfortunately, it relates to an entirely different topic. The fact is that seamen are cared for at all ports of the United States. Application is made to a medical officer of the Service, if such be stationed there, or, "in the absence of such officer, then to the proper customs officer, acting as the agent of the Marine Hospital Service." No *bona fide* seaman who is in need of medical care is ever intentionally refused hospital or office treatment by the Service, so long as he has not abandoned his vocation. The choice of another profession, in which the man believes he can do better, very naturally cuts him off from relief. Boarding-house keepers, longshoremen, bummers, and frauds are ruled out. From such as these complaints of neglect generally come.

"The official reports show that from 1860 to 1878 the tax collected from seamen amounted to \$4,368,757, and the appropriation by Congress, for the same period, \$3,061,303." A singular forgetfulness undoubtedly prevented the mention of the fact that for at least thirteen of these nineteen years the Service was simply a machine, — the toy and prize of politicians; that large sums were expended in that time unwisely and perhaps dishonestly; hundreds of patients were admitted to hospitals without the shadow of right; surgeons and their families were subsisted, and members of Congress, collectors, and other officials entertained, at the public expense; and pickings and stealings were persistently winked at. On the other hand, since the reorganization of the Service in 1873 it has been practically self-supporting. For the fiscal year ending June 30, 1880, 24,860 seamen were furnished relief by the Marine Hospital Service; the receipts were \$399,129.90, and the expenditures \$402,185.49. The receipts were entirely from the collection of hospital dues, with no appropriation from Congress, no such assistance having been received since 1873, and since November, 1873, no deficiency estimate has been presented to Congress; prior to the reorganization from \$150,000 to \$200,000 were appropriated annually. The expenditure of \$402,185 in 1879-80 includes an extraordinary disbursement of \$31,440 for the bedding and outfit of two new hospitals.

In 1869 (before the reorganization) 11,356 patients were treated; the receipts were \$474,719.70, including an appropriation by Congress of \$200,000; the expenditures were \$406,089.23. We find at this day more than twice as many seamen treated at a less total cost, and a service self-supporting.

"Applicants for relief must first satisfy the collector that they have paid their tax for the three months prior to their application for relief; without such evidence they are not seamen according to the law, and have no claims upon the Marine Hospital fund." Only at ports where there are no medical officers is the patient obliged to seek the collector who acts as agent of the Service. The Regulations expressly provide that but *two months' service* are required; that a reasonable absence does not preclude a seaman from relief, provided he has not abandoned his calling; and, moreover, relief to a seaman of a *single day's* service is not refused if he is injured or has been taken sick while in the line of his duty, or in *any* case of emergency where humanity dictates a lenient construction of his case.

"The Service, as a charity, is opposed to the best interests of the sailor in this, that it offers an encouragement to debauch and vice; . . . a large majority of the cases treated are venereal diseases and other con-

sequences of debauch on shore." The high moral tone of this quotation loses some of its point in that the latter part is untrue, the former absurd. According to the statistical tables of annual reports published from 1873 to 1880, the percentage of venereal diseases has not exceeded twenty-four per cent. (varying from sixteen to twenty-four per cent.). Moreover, as the moral and humanitarian aspect of the case is called up by the author, the fact is clear that the sick or disabled seaman, whatever his disease or its cause, is a *patient*, in need of assistance; to be treated as the army surgeon treats friend or foe, *nullo discrimine*. The seaman is a child in manners as he is in facility of falling into temptation; *he is at the same time a human being, and calls for humanity*.

I have criticised some of the statements made in this report. There are others equally baseless and equally absurd. I do not, for want of space, touch the deductions at the close of the report, except to express my dissent from them. Thus far I have looked at this document as it stands. On seeking its authors I find the chairman of the committee to be a physician of San Francisco, *late* Surgeon of the Marine Hospital Service, who resigned "rather than obey orders;" in fact, a man attached by many ties to San Francisco and to the Service — so long as he was allowed to draw his pay in that city. *Hinc ille lacrimæ!* The second is his friend. The third is unknown to fame.

From a somewhat intimate acquaintance with the Marine Hospital Service for eight years, and from an active participation in its duties for more than three, I cannot fail to express my hearty dissent from this report, its statements and conclusions; it bears the impress of malice, and deserves contradiction. On the other hand, *I know* the Service, as now constituted, to be effective and active, and in every way to be working for the good of the seaman; its present chief is wise, honest, and just, and its medical officers, chosen after a rigid examination, are selected from young men who will compare favorably with any in our midst.

I quote the words of Dr. E. J. Doering, *late* Surgeon in the Service, and now in Chicago, in confirmation of the statements I have made: —

"I have been connected with the Service for six years, and am familiar with its workings, and having resigned, and now being engaged in private practice, I have no further interest in this matter than to see justice done to a Service which asks no defense, but desires to be judged on its own merits, and not on the basis of an underhanded attack of one of its enemies, made behind the shield of a so-called committee of the California Medical Society."

FRANCIS H. BROWN,
Late Passed Asst. Surgeon M. H. S.

PODODYNIA.

MR. EDITOR, — In reading the interesting paper by Dr. T. B. Curtis on Pododynia in a recent number of the Boston Medical and Surgical Journal, it has seemed to me rather remarkable that he should have overlooked overstretching of the plantar fascia and an incipient flat foot as a cause of heel-pain in the first case narrated by him, as well as in the second case quoted from Desprès.

Without doubting that such a pain may be of a reflex character in some cases, it is very reasonable to

suppose that in heavy persons, who may perhaps have suffered from a slight injury of the sole, which serves as a starting point, overstretching of the plantar fascia, or an inflammation of slight degree at its posterior insertion, may be the cause of the trouble. Such disturbance might very likely be acquired by those whose duties obliged them to be much on foot, and especially in the case of those who had become rapidly fleshy. In such a case the development of similar trouble in the other foot is not difficult to understand; for, owing to the pain caused by standing, the weight is instinctively thrown upon the better one of the two feet, and when excessive weight is the original cause of the trouble such additional weight thrown upon the other foot might soon cause it to show signs of like trouble.

I had an experience in my own person of the correctness of this explanation when, a few years since, an injury of my left knee caused me to throw too much of my weight upon my right foot. As soon as the state of affairs was appreciated a rubber muscle with adhesive plaster was attached to the inner side of the leg so as to raise the arch of the sole, and after a few days the trouble ceased. I never became aware of any reflex cause, and since the recovery from the trouble in the left knee have never had a return of the plantar pain.

I may further remark that I now have under treatment a lady past the menopause who has of late grown rapidly stout, and who for several weeks has had "pain in the heel" of the right foot, which gradually increased in severity and extended over the region of the plantar arch, being nowhere very well localized, until, at last, walking became almost impossible. When I saw her, a few days since, a similar pain had developed in the left heel, but had not yet extended to the rest of the foot. By inspecting the right foot, undressed and raised from the floor, no local trouble can be detected, and the patient is entirely comfortable; but on extending the foot strongly with one hand, and, with the thumb of the other, making pressure on the inner margin of the plantar fascia, the pain in the heel and in the plantar region is at once reproduced. By directing the patient to stand up and rest the weight on the affected foot, it is at once apparent that there is some flattening of the instep, which is not appreciable when the foot is raised.

Now it is not to be expected that any "rubber muscle" that can be applied to a patient who weighs over two hundred pounds (as is the case with the one here referred to) will do more than palliate the tendency to flattening of the arch under such a strain; but it does *something*, and together with enforced rest for a time will help to cure the trouble. It is working better than I expected in the present instance, and I shall put another "rubber muscle" on to the better of the limbs to-morrow.

One of the causes of the widely-diffused and with-difficultly-located pain about the foot is the displacement of the bones of the tarsus by the spreading of the arch, and it is *this* pain rather than that which is located in the os calcis which, in my experience, interferes with walking.

I had not intended, when I began to write, to inflict so much upon you, but another case occurs to me which helps to illustrate the nature of the initial pain as felt in the receders of these patients.

I remember a gentleman who has had slight but well-marked rheumatic attacks, while exploring the

works of a Nevada silver mine, overstrained the insertion of the tendon of his right deltoid into the humerus. It was a long time thereafter before he could use the muscle without causing a recurrence of pain *limited to the insertion of the tendon*. I gave him anti-rheumatic treatment, but I have no very good ground for belief that it effected a cure. At all events, he got over it in time.

I think that what I have said would warrant the addition of an *eleventh* condition, characterized by "pain in the heel or sole, unattended by any objective symptoms," to those enumerated by Dr. Curtis, and in reading the two cases first enumerated by him I am inclined to place them in this category.

F. A. CASTLE.

NEW YORK, June 9, 1881.

INUNCTION AS A REMEDY FOR ACUTE INFLAMMATION.

MR. EDITOR,—I feel it almost a duty to add my testimony to that of Dr. Parker¹ as to the value of oil or grease as an external application. I have for ten years used it as a matter of routine in almost all forms of acute inflammation of the thoracic and abdominal viscera; also in inflammatory sore throat, abscesses, and some cutaneous eruptions. I generally order lard, which is to be found in every house, simply rubbed upon the skin, and covered over with a piece of flannel. It acts precisely like a poultice, for which it is a most convenient substitute, especially for children. In fact, I almost habitually use it instead of poultices, except in the case of discharging sores and abscesses; in short, wherever the skin is unbroken. If I want a stimulating effect I mix a little salt with it, making a very good substitute for camphorated oil and other liniments. The practice is not at all a new one, but seems to me not as well known nor as much used as it ought to be. The books, as Dr. Parker says, are strangely silent about it, though its efficacy in quelling inflammation is marked, and has the advantage of leaving no depressing effect behind. It is one of those little things of which successful practice is so largely made up, yet so simple and so small as to be almost beneath the notice of the too prevalent school of "intellectual myopes" and medical pundits.

Respectfully yours,

EDWARD T. WILLIAMS, M. D.

ROXBURY, June 18, 1881.

A QUERY IN ETHICS.

MR. EDITOR,—I think it reads "conduct unbecoming and unworthy a member of the Massachusetts Medical Society." Now, I have a medical friend who is a constant contributor to our local newspaper, and his items always end, "Dr. — was called." Week after week from one to a dozen of these interesting paragraphs adorn the columns of this paper. Wounds and bruises are transformed into fearful lacerations, fractures, and dislocations. Difficult surgical operations are reported which never took place except in the mind of the doctor.

Will you, or some gentleman versed in the proprieties which should govern the practice of our noble art,

¹ JOURNAL of June 16, 1881.

give me some idea to what extent we can "blow our own horn" without being liable under the clause first quoted?

I am, very respectfully, your obedient servant,

CANTHARIDES.

LETTER FROM PHILADELPHIA.

MR. EDITOR.—The Philadelphia Medico-Legal Society held its first annual celebration June 9th. Previous to the supper a conversational meeting was held, Dr. E. R. Prall in the chair. The subject of the several points at issue between physicians and druggists were considered, and the best means of meeting the evils of over-the-counter prescribing, unauthorized renewal of prescriptions, substitution and sophistication on the part of druggists were freely discussed. Several of the members of the society, having previously practiced in the country, said that they had found it advantageous to continue dispensing their own medicines in the city; others stated that they had been forced to adopt this course in order to protect their patients from extortionate charges of druggists, and to insure their obtaining the medicines ordered without adulteration or substitution. Dr. G. M. D. Peltz, by invitation, gave a very interesting account of the circumstances which had led him to take this step and dispense his own drugs. After referring to and giving illustrations of the excessive charges, amounting in some cases to a prohibitory tariff, he said that sophistication was very common among ordinary drug-shops; tinctures are generally made from fluid extracts, and not according to the Pharmacopœia; other preparations are likewise improperly made, and of varying strength; very little reliance could be placed upon the freshness or purity of remedies obtained indiscriminately from druggists, whose principal business is selling patent medicines. These remarks were not intended to apply to all pharmacists, but to the large number who are unprincipled and are governed solely by self-interest. Having decided to keep his own medicines, Dr. Peltz found that the wholesale druggists, with one exception, refused to give him a price-list, or to sell to him on the same terms as to retail druggists. This decided him; he accordingly laid in a stock of good drugs, and set to work making his own preparations according to the United States Pharmacopœia. Contrary to his expectations, his patients preferred to send to him for their medicines, rather than to trust to a disinterested apothecary to put them up. An incidental advantage of this plan is that it makes the doctor an excellent collector, which in dealing with many people is of prime importance; a direct advantage is, however, that the physician knows exactly what the patient is taking. The doctor had carried on this method only for six months, but had found it so successful that he was glad he had tried it, and was determined to continue it.

A vote of thanks was unanimously tendered Dr. Peltz for his interesting and important communication. In the discussion generally an evident want was exhibited for better control over the physician's prescription. Besides the method already referred to, it was stated that a physician with a large office practice employed a graduate in pharmacy to call at the close of his office hour for all the prescriptions, which had been retained on file; these were now compounded *secundum artem* and delivered at the patients' residences, the physician

keeping his prescriptions. This plan has been in practice several years, and works well. The members of the society seemed much interested in the remarks made upon the subject, and it was evident that the example cited would have a number of followers. A supper terminated the evening's exercises, to which about forty members sat down.—a large number, considering the fact that the night was very stormy and unpropitious.

From the above it is seen that in this city the irrepressible conflict continues. The animus of the druggists may be inferred from the fact that at a recent meeting of their board of trade a resolution was adopted declaring that in their relations to the public they occupied an equal standing with physicians. This was apparently in reply to a resolution recently adopted by the Philadelphia County Medical Society asserting the fact that, in compounding prescriptions, the druggist acts simply as the agent of the physician.

An important step has been made by the Faculty of Jefferson College in lengthening the term four weeks, making the annual commencement come at the last of March or early in April, the lectures beginning as usual with the preparatory course in September. There are some changes in the roster in the arrangement of didactic and demonstrative lectures, which are to begin at nine o'clock each morning instead of ten, as heretofore.

The alterations in the building are going on rapidly; by which it is said that the seating capacity of the two lecture halls will in each be increased by about one hundred seats.

The case of the young girl (referred to on page 284 of this volume of the JOURNAL) who was tried for infanticide last week resulted in acquittal. It was testified that she had made application at a number of institutions for attendance during confinement, but was uniformly met with refusal, and was taken from the street by two poor women, who gave her shelter. The villain who brought her to Philadelphia had deserted her and left her, friendless and without means, in her unfortunate condition, to the mercy of strangers. The case excited the attention of the Women's Christian Association, who provided counsel for her at the trial, and sent her to her friends after acquittal.

Bishop Stevens has announced his intention of instituting a home for foundlings in this city during this summer, preparatory to inviting the assistance of the clergy and laity in the work next fall.

At the last meeting of the County Medical Society Dr. Carl Seiler exhibited a new form of office battery for galvano-cautery. Twelve pairs of plates (about four by six, zinc and carbon), connected for intensity, are dropped into and removed from the electrolyte contained in two large jars, inclosed in a box, by means of a treadle which is counterbalanced. By this means the physician does away with the need of an assistant, as the treadle is worked by the foot; the amount of depression controlling the degree of heat by regulating the immersion of the plates into the fluid, the current being started or stopped almost instantly. For operations in air-passages, requiring the actual cautery, this form of battery is the most convenient that has yet been brought before the profession; and in ordinary cases it would seem to be much simpler and easier of application than even the thermocautère of Paquelin.

Mayor King has determined that the coming Fourth of July shall be celebrated in this city in a more rational

manner than heretofore, and has therefore notified dealers in fireworks that they will be prosecuted, according to the law of 1721, for exposing certain explosives for sale; and every one is forbidden to fire pistols, bombs, crackers, etc., upon the public streets. A year ago, as the result of the general use of small toy pistols, nearly twenty children perished from tetanus in this city alone; and several columns in the daily papers were occupied with a list of the accidents to life and property, which we hope will be much less on the next "Independence Day."

Among those who will attend the International Congress at London from this city, we notice Professor Gross and Dr. S. H. Gross; Dr. J. Minis Hays, editor of the *American Journal of Medical Sciences*; Dr. Horatio C. Wood, editor of the *Philadelphia Medical Times*; Dr. J. Solis Cohen, Dr. R. A. Cleemann, and others.

LETTER FROM VIENNA.

OBSTETRIC INSTRUCTION.

MR. EDITOR, — The manner of teaching obstetrics in the wards of the General Hospital of Vienna may be considered as extremely advantageous for advanced students, as most of those who go there from America are.

An operative course in obstetrics on the dead body is given by Dr. Powlik, Prof. Karl Braun's assistant. This allows each student the opportunity of performing the various operations at least once, and sometimes twice.

An operative course very similar to this is given by Dr. Richardson at the Harvard Medical School.

Those students who have taken the operative course are permitted to take a touch course under Dr. Powlik by paying an additional fee. This is really a very instructive course, as very few of the students have had the opportunity of examining so many pregnant women previous to delivery as they get here. Dr. Powlik usually takes four students, one hour each day, and assigns to each for examination a pregnant woman. Each student makes a thorough external examination of the abdomen by palpation and the ear, and reports upon what he has found, the position of the child and the number of children being the things sought for by abdominal examination. His diagnosis is then confirmed or shown to be erroneous by Dr. Powlik and the other students. Especial stress is laid upon making out the position by grasping the child's neck between the thumb and fingers of the right hand, and by deep pressure, not sufficient to be painful at all to the woman, distinctly feeling the chin of the child, which, by approximating the thumb and fingers underneath the neck, can be easily grasped, and in most cases readily moved from side to side. This point, I think, has never been described by any writer.

After the external examination is finished the diagnosis is confirmed, as far as possible, by an examination per vaginam. Most of the women are in the eighth or ninth month of pregnancy, and are examined by Dr. Powlik previous to the student's examining. The student reports upon what he finds per vaginam, namely, the height and softness of the fornix, the size of the os, the length of the cervical canal, and whatever may be found on the presenting part, if it may be felt. From these the student gives his opinion as

to the time of gestation, and about when the woman may be confined. Each student taking this course has the opportunity to examine four women each day for one month. The fee is \$22.00. All students who have taken out Professor Braun's ticket, which is a general one, similar to a matriculation ticket, are permitted to examine pregnant women twice per week for an hour at a time, in one of the large wards. But there is such a rush of students to this that it is hardly worth attending, as one can rarely get an opportunity to examine more than one patient, even if he may be so fortunate as to secure one. There are about ten confinements a day in the hospital, and it is only every third day that pregnant women are admitted in Braun's wards, to which the students have recourse, so that really the students do not have a very large number of confinement cases to attend. Those students who desire to take cases can do so by leaving their names on the ward list, and cases are assigned them. Many of the students do not care for normal cases, and if they find the case assigned them is normal they will often leave it to one of the midwives who are attached to the ward. If the student finds he has an abnormal case, or it is likely to be instrumental, then he watches it along, hoping that he may be permitted to use the instruments, if it should come to that. If it is a simple forceps case he is often allowed to operate, but if a difficult forceps or some other operation it is usually done by Dr. Powlik, unless it is near the hour for Professor Braun to lecture, when the latter performs the operation and uses the case as the topic of his lecture.

Of these different courses the one which perhaps is of the most value to students is the touch course, since it cannot be practiced in our country as it can be at Vienna, where so many pregnant women are brought together. If it should be attempted to any extent at our lying-in hospitals the probable result would be a depopulation of the hospitals in a very short time, as in our cities there are many places where women can be confined with good care, while at Vienna the General Hospital is about the only place for them.

I will merely speak of one very interesting case which was operated upon by Professor Braun at his clinic this winter.

A woman of thirty-five had been in labor thirty-six hours, and was nearly exhausted. Pains very feeble. She was delivered by forceps with some difficulty, when it was suddenly ascertained that the uterus was ruptured. When this accident occurred was uncertain. The only thing to do was to open the abdomen and remove the uterus, which was done. The uterus was drawn out through the abdominal opening and divided by the galvano-cautery, so as to make the hemorrhage as slight as possible. The division was made just above the cervix, which was left behind in the abdomen. There were a number of clots in the abdomen, but not much hemorrhage from the operation. Carbolic spray and dressing were used.

No obstruction was determined to cause the rupture, which occurred at the right posterior portion, and extended upward about three inches from the cervix. The woman lived about eighteen hours after the operation. The child was nearly dead when delivered, and could not be resuscitated. It was normal as regards size and shape. The presentation was considered normal, with no obstruction.

ROBERT B. DIXON, M. D.

Deaths reported 2590 (no reports from Cincinnati); 1118 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 677; consumption 314, diphtheria and croup 201, lung diseases 188, diarrhoeal diseases 165, scarlet fever 81, small-pox 51, cerebro-spinal meningitis 45, measles 39, typhoid fever 32, malarial fevers 22, whooping-cough 19, erysipelas 10, typhus fever seven, puerperal fever five. From *small-pox*, New York 23, Philadelphia 20, Chicago four, Pittsburgh two, Brooklyn and Boston one. From *cerebro-spinal meningitis*, New York and St. Louis 11, Chicago eight, Providence three, New Orleans, District of Columbia, Pittsburgh, and Milwaukee two, Philadelphia, Brooklyn, Worcester, and Webster one. From *measles*, New York 21, Baltimore five, Brooklyn and Chicago three, New Orleans and Providence two, Philadelphia, Buffalo, and Milwaukee one. From *typhoid fever*, Chicago, St. Louis, and Baltimore five, New York, Philadelphia, and Brooklyn three, Pittsburgh and Lowell two, Boston, New Orleans, District of Columbia, and Charleston one. From *malarial fevers*, New Orleans six, Brooklyn four, New York three, Baltimore and Charleston two, St. Louis, District of Columbia, Pittsburgh, Buffalo, and Milwaukee one. From *whooping-cough*, Philadelphia five, Baltimore four, New York three, Brooklyn and Chicago two, Boston, Buffalo, and Attleborough one. From *erysipelas*, New York and St. Louis three, Philadelphia, Brooklyn, Buffalo, and Malden one. From *typhus fever*, New York seven. From *puerperal fever*, St. Louis two, New York, Chicago, and Nashville one.

Thirteen cases of small-pox were reported in Brooklyn, 42 in Chicago, three in Boston, 11 in Pittsburgh; diphtheria 32, scarlet fever 11, in Boston; scarlet fever 19, diphtheria 10, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,037,824 (population of the State 1,783,086), the total death-rate

for the week was 18.24, against 17.75 and 17.62 for the previous two weeks.

For the week ending May 28th in 149 German cities and towns, with an estimated population of 7,763,482, the death-rate was 26.1. Deaths reported 3895; 1856 under five: pulmonary consumption 565, acute diseases of the respiratory organs 425, diarrhoeal diseases 159, diphtheria and croup 131, scarlet fever 74, typhoid fever 47, measles and *rötheln* 39, whooping-cough 33, small-pox (Königsberg two, Munich, Berlin six, Kottbus, Hamburg, Cologne, Aachen two) 14, puerperal fever 13, typhus fever (Tilsit, Erfurt) two. The death-rates ranged from 17.8 in Cassel to 43.3 in Augsburg; Königsberg 34.7; Breslau 32.5; Munich 33; Dresden 19.4; Berlin 25.8; Leipzig 26.8; Hamburg 26.6; Hanover 21.2; Bremen 32.9; Cologne 23.4; Frankfort 18.6; Strasburg 35.3.

For the week ending June 4th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20.3. Deaths reported 2967: acute diseases of the respiratory organs (London) 249, measles 116, whooping-cough 91, small-pox (London 82) 85, scarlet fever 60, diarrhoea 43, fever 37, diphtheria 14. The death-rates ranged from 12.6 in Brighton to 25.5 in Manchester; Leeds 17.8; Birmingham 17.9; London 20.5; Liverpool 21.9; Sheffield 22.7; Bristol 23.9. In Edinburgh 20.8; Glasgow 22.7; Dublin 26.4.

In the 21 chief towns in Switzerland, for the week ending June 4th, population 479,934, there were 26 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 23, measles 12, typhoid fever five, diphtheria and croup four, small-pox four, puerperal fever three, whooping-cough three, scarlet fever two. The death-rates were: Geneva 9.9; Zurich 29.1; Basle 28.5; Berne 26.9; St. Imier 50.8.

The meteorological record for the week in Boston was as follows:—

THE LATE DR. C. T. COLLINS. — RESOLUTIONS OF RESPECT BY THE BERKSHIRE MEDICAL SOCIETY.

WHEREAS, The death of the late Dr. C. T. Collins has removed from this society one of its oldest and most honored members; —

Resolved, That the Berkshire Medical Society and the profession at large have sustained an irreparable loss; the community in which he lived a valued and honored citizen; and the sick and suffering a successful and beloved physician.

Resolved, That we ever bear in mind his genial presence and wise counsels at the meetings of the society, of which he was one of the most regular attendants.

Resolved, That we extend to the family and friends of the deceased assurances of our grief and deep sympathy with them in their great affliction.

Resolved, That the foregoing resolutions be published in the county papers and in the Boston Medical and Surgical Journal.

W. W. LEAVITT, }
F. K. PADDOCK, } Committee.
H. J. MILLARD, }

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 18, 1881, TO JUNE 24, 1881.

MIDDLETON, J. V. D., major and surgeon, having reported in person is assigned to duty at Fort Hays, Kans., relieving Assistant Surgeon Munn. S. O. 122, Department of the Missouri, June 21, 1881.

GARDNER, W. H., captain and assistant surgeon. Granted leave of absence for four months on surgeon's certificate of disability. S. O. 138, A. G. O., June 18, 1881.

MESS, C. L., captain and assistant surgeon. When relieved by Surgeon M. O'Brien to proceed to Fort Bayard, New Mexico, and report to the commanding officer for duty. S. O. 122, C. S., Department of the Missouri.

DEWITT, C., captain and assistant surgeon. Granted leave of absence for four months. S. O. 137, A. G. O., June 17, 1881.

BOOKS AND PAMPHLETS RECEIVED. — The Disposal of the Dead, a Practical Catechism. By Edward J. Birmingham, M. D. New York: Birmingham & Co., 1881.

France and French and Studies in the Lower Animals. By George M. Beard, M. D. (Reprint.)

Principles on the Duty and its Preventible Causes. By H. Warner, M. D. (Reprint.)

Remedies in General Phases of Poisoning, by Alcohol. By I. C. W. Jones, M. D. (Reprint.)

Principles of the Interior, Bureau of Education. Library A 14.

Principles of Medical Education, being the Doctorate Address at the First National Annual Commencement of Rush Medical College, June 21, 1881. By J. Adams Allen, M. D.

Principles of Surgery in Medicine. An Address by E. C. S. Jones, M. D. (Reprint.)

A Lecture on the Localization of Diseases in the Spinal Cord, delivered before the Anatomical and Surgical Society of Brooklyn. By Edward C. Seguin, M. D. (Reprint.)

Fourteenth Report of the Medical Staff of St. John's Hospital. Submitted at the Annual Meeting, April 4, 1881. Lowell, Mass.

Hysteria in Boys, with the Report of a Case. By S. Henry Dessau, M. D. (Reprint.)

The Ninth Annual Report of the Board of Directors of Zoological Society of Philadelphia. Read at the Annual Meeting of the Members and Loan-Holders of the Society, April 28, 1881.

The Ninth Annual Report of the Charlestown Free Dispensary and Hospital.

The Differential Diagnosis of Fractures and Dislocations of the Femur at the Hip-Joint. Tabulated by H. Augustus Wilson, M. D. (Reprint.)

Observations on Pertussis, based upon an Analysis of Three Hundred and Sixty-One Cases. By S. Henry Dessau, M. D. (Reprint.)

A Medico-Legal Treatise on Malpractice, Medical Evidence, and Insanity, comprising the Elements of Medical Jurisprudence. By John J. Elwell, M. D. Fourth Edition, revised and enlarged. New York: Baker, Voorhis & Co., 1881.

Simple Methods to Stanch Accidental Hemorrhage. By Edward Borek, M. D. (Reprint.)

The Hygiene of Emigrant Ships. By Thomas J. Turner, M. D., Medical Director United States Navy. Read before the American Public Health Association, December, 1880, at its Annual Session in the City of New Orleans, La. Boston: Rand, Avery & Co., 1881.

Contributions to the Physiology of the Spinal Cord and Adjacent Parts. By George B. Wood Field, M. D. (Reprint.)

A Centennial Address delivered in the Sanders Theatre, at Cambridge, June 7, 1881, before the Massachusetts Medical Society. By Samuel Abbott Green, M. D. Groton, 1881.

Announcement and Catalogue of the Medical Department of Dartmouth College, Hanover, N. H.

On the Early Diagnosis of some of the Organic Diseases of the Nervous System. By E. C. Seguin, M. D. (Reprint.)

Clinical Illustrations of Favus, and its Treatment by a New Method of Depilation. By L. Duncan Bulkley, M. D. (Reprint.)

Rupture of the Urethra, with Extravasation of Urine, etc. By Thomas R. Wright, M. D. (Reprint.)

The Treatment of Strains and Sprains by Collodion. By Albert N. Blodgett, M. D. (Reprint.)

Reports of the Executive Committee, Physician, Treasurer, and House Committee of the Sea Shore Home, for the Summer of 1880. Boston, 1881.

Monthly Weather Review, April, 1881. General Weather Service of the United States.

L. v. Lesser. Demonstration zur lokalen Anaesthesirung. (Separat-Abdruck.)

Sixth Annual Announcement of Mehany Medical Department of Central Tennessee College.

A Treatise on the Diseases of the Nervous System. By William A. Hammond, M. D. With one hundred and twelve Illustrations. Seventh Edition, re-written, enlarged, and improved. New York: D. Appleton & Co., 1881.

MEDICAL EXPERT TESTIMONY.¹

BY WALTER CHANNING, M. D.

PROBABLY most of those present have read the valuable paper of Dr. F. W. Draper on Medical Expert Testimony, published in the Medical and Surgical Journal of November 4, 1880. This paper, which is remarkably clear and exhaustive in the presentation of the subject, shows how defective our present system is, and gives the draft of a new law, which is intended to remedy these defects. We have been, in times past, favored with many papers on the subject of expert testimony, but, notwithstanding, I feel that it is none the less the duty of every one to aid in correcting what may be regarded as a public evil, and to keep the ball in motion until the needed reform is instituted.

The principle of expert testimony, in this country, is theoretically an eminently fair one. To all suits there must of necessity be two parties, to all questions two sides, and, *primâ facie*, there is, therefore, no theoretical objection to each side calling such expert witnesses as it may choose. It does not follow, by any means, that one side is entirely in the right, for the matter in hand, looked at from different points of view, appears very different. The difficulty in a law suit is, however, that one side must be so overwhelmingly right that the minds of the jury shall be satisfied that such is the case. To do this it is necessary, in some cases, to resort to dishonest methods. The question is, How may we influence the twelve ignorant men whose opinion is to decide the case? No ordinary arguments are sufficient, in some cases even truth itself is powerless. We do not strive to present the matter as it really is, and leave it to be decided on its merits, but endeavor to color it in such a way that it shall appear what we wish it to be.

An honest medical man will be put to the greatest embarrassment in our courts to-day if, regardless of all personal feeling, he persistently asserts what he regards as strictly the correct and scientific opinion of the matter to be passed upon. To go more into detail, we will assume that a physician is asked to go into court as an expert. The lawyer who is to try the case goes to him and frankly states the various circumstances. The very fact that the lawyer goes to him is complimentary, and at once places them on good terms. As the lawyer details the facts, unconsciously, and with the best of motives, the expert finds himself endeavoring to disengage from the mass of evidence submitted to him sufficient data to weave into a thread of as great consistency and strength as possible in favor of the lawyer's side. He will not go out of his way, very naturally, to put himself on the other side of the case. Perhaps the facts have been a little colored to make a more favorable impression upon his mind; he is not unwilling to add a laurel to his wreath or a snug sum to his coffers by appearing in court as a medical expert, and altogether he falls a not unwilling prey to the legal hook that has been skillfully baited for him. It may be because I lack imagination, I must at any rate confess that it is hard for me to imagine a case in which an expert would not be ready to testify unless the lawyer or the case itself

were of such a character that the association would be an injurious one. Given, a lawyer with an equally respectable reputation with that of the physician, and the latter, in nine cases out of ten, would accept service in his cause. Once having entered the field as an ally and he will find himself even more endeavoring to put those such points as are in his favor, and rejecting those which are in the favor of his antagonists.

We must grant that it is right for counsel to engage medical expert testimony, and for physicians to accept service at their solicitation. The difficulty is that this principle of testifying for one side is frequently carried so far that the medical expert clearly shows himself to be entirely given over to this side, and tries by every means in his power to defend his opinions given in its favor, and ignores any evidence, scientific or otherwise, in favor of the other. In cross examination he will resolutely adhere to opinions invented on the spur of the moment, with scientific arguments equally manufactured out of whole cloth, for this occasion only. To see two medical men of fair reputation opposing each other's testimony with the most fallacious and far-fetched of theories is one of the strange spectacles presented in our court rooms. Place these same men together under ordinary circumstances and they would be found in full agreement on points to which, on the witness-stand, they attach a diametrically opposite value. The consequence of this conflicting testimony, of these strange and fallacious statements, and the invariable agreement of the testimony with the argument the lawyer is trying to establish, is to detract seriously from the worth of medical evidence in court. Such evidence can, however, be said to be honestly given; for the time being the expert becomes a party to the suit, and is so far infected by the spirit of the argument which the counsel follows that he is able to believe that what he desires to be right is right. There is another grade of experts, many steps lower than these to whom we refer, that are absolutely dishonest, and who, though possessing little weight professionally, are instrumental in bringing medical expert testimony into disrepute. These men will testify on any subject, be it pathology, surgery, insanity, or microscopy. They hang about courts, are eager to offer their services, and will sell themselves to the highest bidder. The court and the jury shrug their shoulders at the lame statements made by such men, and, unfortunately, when the honest expert appears on the stand he finds himself listened to with a lack of attention, sometimes even impatience. "Oh!" one can imagine the jury saying to themselves, "it makes no difference what the doctors say, they never agree." As the case now stands medical expert testimony possesses little dignity and often degrades the science of medicine. The word of the expert is doubted, and his scientific statements are subjected to the same vulgar cross-examination as those of the meanest witness in a bar-room brawl.

Interested as I am in a specialty where expert testimony is of great importance, and, I may say, in constant demand, the necessity of a pure and dignified system comes home to me with great force. Perhaps on the subject of insanity the average doctor, in times past, has been more willing to express his opinion than any other. Insanity being a disease of the most obscure organ of the body, whose symptoms are manifested by changes in the conduct or character of man. Up to the beginning of the present century the theolo-

¹ Read before the Norfolk District Medical Society, December 28, 1881.

gian, the metaphysician, and lawyer were in the habit of advancing various vague and indefinite theories which became, in one way or another, the common opinion of the world in general. Every man knew what sanity was, and insanity being merely a greater or less transposition of the elements of which it was composed, it followed that it was to be viewed in a somewhat similar light. Leaving out the theories of the theologians and metaphysicians, it is interesting to consider for a moment, as having a direct bearing on the question under discussion, a few of the legal definitions of insanity. The English law at first recognized only two kinds of insanity, known as idiocy and lunacy, the subjects of which were *non compos mentis*. Lord Coke pointed out four classes of persons who could be regarded as in this condition, namely: (1.) Idiots. (2.) He that wholly loseth his understanding. (3.) A lunatic that sometimes hath and sometimes hath not his understanding. (4.) He that is drunken. Later Lord Eldon asserted that a person was *non compos mentis* if incapable of managing his own affairs. Still later Lord Hale attempted to define total and partial insanity. The latter being a condition where there was still as much reason as in a child of fourteen. According to Lord Hale, partial insanity would not exempt from punishment in a criminal case. In 1723 Mr. Justice Tracey describes a true lunatic "as a man that is totally destitute of memory and understanding, and doth not know what he is doing no more than an infant, than a brute, or a wild beast." Some time after this the power of distinguishing between right and wrong was regarded as the necessary test, then the presence of delusion, the understanding of the nature and quality of the act, etc. Though to-day our courts do not blindly follow the dicta of the old English judges, they still are largely influenced by them, and often counsel rest the whole strength of their arguments on these wholly inadequate and fallacious tests. That insanity is, however, a physical disease, and therefore a subject to be considered by the physician, is a fact more clearly brought out at every trial where experts of high character appear on the stand and fair-minded counsel conduct the examination. The extreme difficulty of accurately defining insanity and the old superstitions will probably render the position of the insane expert in court a most uncomfortable one for a long time to come. In an ordinary case, for instance, as to the necessary or probable consequences of a surgical injury, it is easy enough for a physician of extensive experience to give exact, definite evidence, which can be sustained under any and all kinds of cross-examination. Should opposing counsel seek to invalidate his testimony he can find no authorities to bear him out, and he must yield to the force of pure science. But in a case of insanity authorities differ on so many points that it is easy to oppose the statement of one with that of another. Furthermore, a man's motives, conduct, or character can be explained in a great variety of ways, and at present, in a doubtful case, involving large interests, courts generally prefer to take the testimony of the lay friend or relative to that of the expert, who, however learned, has had no opportunity to make a personal examination, and, therefore, cannot be so competent to pass judgment on the statements of others. The fact is entirely forgotten that the more a man studies character and treats cases of insanity the greater must be his power of detecting slight shades of difference.

In cases of insanity it is customary to ask the most intricate and incomprehensible "hypothetical questions," as they are called. In some instances they stretch out to an hour in length. The counsel of either side frames the question after such a fashion that it must inevitably be answered according to his wishes. It is, in fact, getting the expert to express his opinion on the case at issue, for the points in the hypothetical question are facts taken from the evidence. The original object of such a question was to draw out impartial testimony, but it is entirely lost by the course counsel pursue. The jury are confused by the long question, they hear the expert stultify himself, and are left with even a more imperfect knowledge of the case than they had before.

The class of unscrupulous, self-styled experts, already spoken of, are more willing to testify in cases of insanity than any others, and I have myself heard them express opinions and give definitions of insanity entirely unheard of up to the time they took the witness-stand. It may truthfully be said that a case of insanity is rarely tried in which there is not some incompetent medical witness called, and unless we can find some way of eliminating these bad men from our court-rooms it will grow more and more uncomfortable to appear on the witness-stand.

I give below the draft of the law presented in Dr. Draper's paper, which I hope will be freely discussed. Certainly some law is necessary to properly regulate medical expert testimony. I wish that some kind and period of experience were necessary to render it possible for a physician to appear in court as an expert. For instance, some such clause as this might be added to a good law: "No medical practitioner shall be regarded as competent to appear as an expert in court unless he can clearly show that he has had a continuous experience of at least ten years in the active practice of the branch of medical science in which he is called to testify." A certificate from the faculty of a medical school embodying these facts would also be a good requirement.

The original draft of the accompanying law was made by a member of the Massachusetts Medico-Legal Society:—

AN ACT IN RELATION TO MEDICAL EXPERT TESTIMONY.¹

Be it enacted, etc.

Section 1. In any action, suit, or proceeding, civil or criminal, in which the testimony of a medical expert witness is desired by the parties, they may at any time before the trial file in the clerk's office a written agreement that such witness shall be summoned, designating him by name if agreed upon. The clerk shall thereupon issue a subpoena to the person designated, to be served in the manner provided by law. As soon as may be after service thereof the witness shall make such examination of the case as may, in his judgment, be necessary and practicable, and he shall attend, as commanded in the subpoena, and answer such questions as may be put in relation to the case.

Section 2. If no person is designated by the agreement of the parties, the court, or any judge thereof in chambers, or in vacation, in any county, upon the filing thereof, shall designate a proper person, learned in the science of medicine, to be summoned as such expert

¹ This act was published in connection with Dr. Draper's paper in the JOURNAL for November 4, 1880.

witness, and the clerk shall thereupon issue a subpoena as hereinbefore provided. If the parties do not agree that a medical expert witness shall be summoned in the case, the court or judge, upon motion of either party and upon hearing, may determine the question, and may designate the person to be summoned, if any, as hereinbefore provided.

Section 3. Such witness shall be paid for his attendance, travel, and services a reasonable compensation, to be allowed by the court, and paid out of the treasury of the county. In all civil actions and proceedings the defeated party shall be liable to refund the amount so disbursed, and after final judgment an execution may issue against him therefor in favor of the county commissioners, or, in the county of Suffolk, the city of Boston.

Section 4. In any case the court, upon its own motion or for cause shown, may order more than one, and not exceeding three persons, to be summoned as medical expert witnesses, and such additional witnesses shall be designated and summoned, and shall perform the same services and receive the same compensation as hereinbefore provided.

[Section 5. In any criminal proceeding the defendant may call and examine other medical expert witnesses in addition to those hereinbefore provided for, but at his own cost, and in such case other medical expert witnesses may be called and examined in behalf of the Commonwealth.]

Section 6. No medical expert witness shall be admitted to testify before any court or magistrate except as hereinbefore provided.

OTIS'S TREATMENT OF STRICTURE OF THE URETHRA.¹

BY GEORGE W. GAY, M. D.
Surgeon to Boston City Hospital.

OTIS's method of treating stricture is a combination of divulsion and urethrotomy. It is designed for all classes of the affection located anterior to the membranous portion of the urethra, and aims at a radical cure.

The operation is performed by putting the stricture on the stretch, slightly cutting it with a concealed blade, and then at once dilating it to a little more than the full size of the normal canal, this having been previously determined by the use of the urethra-meter. The calibre of the canal is to be maintained by the passage of steel sounds till the rent or incision is healed, when, if the operation has been properly performed, and the after treatment faithfully carried out, the stricture, in nine cases out of ten, is permanently cured.

The operation may usually be done without an anæsthetic. The patient is confined to the house but a few days, and in the lighter cases not at all. Dr. Otis claims that accidents are comparatively infrequent, and the danger slight. He has operated in over seven hundred cases "without a death or any permanent disability." But it should be noted that in several of his cases the constriction was so slight that the necessity for an operation may well be questioned. It will be very difficult, for example, to convince practical surgeons that a urethra which admits a No. 36² steel sound requires cutting so that a No. 38 will pass; or in

more general terms that a urethra which takes a No. 30 or over requires any operation to allow of the passage of a larger instrument.

Although our experience in this method of treating stricture is limited, yet it is quite sufficient to justify the opinion that in *deep* strictures it is by no means free from danger, and should be resorted to only after other and safer modes of treatment have failed.

CASE I. A robust man, twenty-three years of age, came under my care in October, 1879, with an obstinate stricture of the urethra of four years' duration. It followed gonorrhœa, and was located in the bulbous portion. The symptoms were: frequent and painful micturition, constant urethral discharge, a heavy dragging sensation over the bladder, and urine loaded with pus and triple phosphates.

The urethra was extremely sensitive and the stricture unyielding, so that after six months' constant efforts, twice a week, at gradual dilatations, I could only pass a No. 22 sound. As the symptoms were only partially relieved and his nervous system was breaking down, a more radical treatment was indicated.

In June, 1880, I cut and dilated the stricture till a No. 31 steel sound readily passed through it, after the meatus had been divided.

The second day after the operation this patient had chills followed by partial suppression of urine, fever, emaciation, and loss of strength. During his convalescence he had an attack of epididymitis, and subacute inflammation of the bladder, so that it was six or seven weeks before he regained his usual health. He now, at the end of a year, passes No. 24 sound once a fortnight; micturition is free and easy, and his only trouble is a little of the old dragging sensation in the region of the bladder.

CASE II. Mr. B. had gonorrhœa twenty-five years ago, but had no trouble in passing water till within five years. He was admitted to the hospital in September, 1880, for complete retention, which was relieved by aspiration, catheter, and hot bath. A week later the patient was etherized, the urethra dilated sufficiently with Gouley's sound to allow the use of Otis's urethrotome. A stricture two inches from the meatus, and another in the bulbous portion, were then cut and dilated till a No. 25 readily passed through them.

The patient soon began to have chills and high temperature, followed by loss of strength, and emaciation. The sound could be used but a few times, as an abscess formed in the perinæum, which required opening; fortunately it did not communicate with the urethra, and soon healed.

He was laid up three months, but now, eight months after the operation, uses a No. 24 sound, has no trouble in passing water, and considers the operation a great success.

CASE III. Mr. C. entered the hospital in October, 1880, with a stricture in the bulbo-membranous urethra which admitted only a small bougie. It followed a gonorrhœa about seven years ago. Dr. Thorndike performed Otis's operation on the 18th of October, cutting and dilating the stricture up to No. 26. Operation followed by chills, some hæmorrhage, retention, and high fever. Pyæmia set in and eight large abscesses were opened within three weeks. They were located on the arms, legs, and back; none were in the vicinity of the stricture. The patient was delirious, lost flesh and strength, and came very near losing his life. There were no other cases of pyæmia in the hospital at the

¹ Read before the Boston Society for Medical Observation.

² The numbers refer to the French scale.

time; on the contrary the sanitary condition of all the wards was good. Three months after the operation he was occasionally using a No. 25 sound, micturition was normal, and his general condition was satisfactory.

In October I operated on another patient, who had two strictures admitting, respectively, a No. 9 and 12 sound. No. 28 passed easily after dilatation. He had a chill within twenty-four hours, but no further trouble while under observation. The patient having been discharged from the hospital for misconduct at the end of ten days the case is incomplete.

The above cases include all that have been treated by this method in the City Hospital thus far, and the experience is not such as to encourage further trial. The strictures were fair samples of those most commonly met with in practice, but the accidents were much more serious than those which usually follow internal urethrotomy or division as formerly practiced.

The grave complications in the above cases were undoubtedly due to the great violence done to the deep strictures of the perineum. The walls of the urethra were widely torn, the nerves and blood-vessels were stretched and lacerated, and the cellular interspaces were opened up, thereby furnishing depots for the collection of urine, blood, and pus. These fluids rapidly decompose, infiltrate the tissues, and furnish all the conditions necessary for septic poisoning.

Although our patients are at present in a very satisfactory condition as regards their strictures, it is as yet too soon to determine whether the improvement will be permanent. But even if a radical cure should be the result in all of them, we cannot but feel that the danger attending this operation, when performed as directed by its distinguished author, is too great to justify its use in ordinary cases of deep strictures of the urethra.

SOME OBSERVATIONS ON THE SURGICAL TREATMENT OF RECTAL AFFECTIONS.

BY WALTER FEA, M. D., OF CAMBRIDGE, MASS.

THE frequent occurrence, pain, and discomfort of rectal diseases makes any contribution tending toward curing or alleviating them more speedily, thoroughly, or certainly, not wholly unwelcome. Several cases of rectal diseases which had been unsuccessfully operated on have lately come under my care, and as the writer has had some opportunities to compare the methods and results of the surgical treatment of these affections here and elsewhere, he has deemed it worth while to note the advance that has been made in this particular branch of surgery.

Said a well-known local surgeon in an amphitheatre before a class of students, "the operation for fistula is simple, any one can do it. Mr. — can do it. Here, shut up this fistula," after he had introduced a director through the external and internal openings. The rapid pacing of a pledget of lint and a T bandage made the performance seem simple enough. But this very patient soon after leaving the hospital returned with a recurrence of his malady, which had been experimentally but not thoroughly operated on. So it was not so much healed by so simple an operation as we were led to believe it would be.

Symptoms of this, that in performing the operation

for anal fistula it is sufficient to divide the parts between the external and internal openings, regardless of farther-reaching sinuses, is not followed by beneficial results, except in a few persons of a strong, healthy constitution. His theory, which has been entertained by some authors, that a fistulous sinus running up above the internal opening can be safely left untouched, is not borne out by experience. Failure of the operation thus performed is the result in the majority of cases. The inference to be drawn is obvious.

As a reward of an imperfectly-performed operation for anal fistula we have often seen a fresh sinus appear directly beneath the one operated on, and perhaps nearly cicatrized, or the wound not heal, owing to a branch or farther-reaching sinus which had not been properly laid open.

There is a distinction to be made whether a discharge comes from a healing, pus-secreting wound, or whether, coming from another source, it courses over a healing surface. In the latter case the discharge may catch under the healing edge of the wound, burrow, and finally form a sinus beneath the healing surface.

The old and unjustifiable process of excision of the tube-like fistulous track, as practiced now by an eminent professor of surgery in Paris, and also by a noted surgeon in this neighborhood, will often be followed by failure if a lateral branch sinus exists, which has to be cut across in the operation; and this method cannot be commended, since it shows an ignorance of the pathology of anal fistula, and non-success is the usual result.

In a healthy subject an uncomplicated anal fistula occasionally heals spontaneously, or with the simplest treatment; so it does sometimes by various caustics, injections, ligatures, elastic or otherwise, but the result by these means is always doubtful. In a complicated case, as frequently occurs, the free use of a cutting instrument is our main-stay, and we can never make sure of the result of a case unless we use it. To guarantee a cure the main and branch sinuses must be freely laid open, and the edges of the wound liberally trimmed off.

If severe hemorrhage is apprehended after incising tracks reaching far up the bowel, the screw tourniquet with twine, as Luke's, or, better, the elastic ligature, may be used for cutting through the cul-de-sac above the internal opening. The solid elastic ligature, with a metallic ring, is quicker in action, easily applied, and absolutely painless. The most successful prefer usually to cut, and depend on efficient plugging to arrest the hemorrhage.

Beyond a thorough and solid packing of the wound with absorbent cotton (not lint as is used here), which serves greatly to consolidate the lax tissues, the wound requires but little active after-treatment, but jealous care and watching must be observed to detect early any small or perhaps unnoticed branch sinus.

The after-treatment is often delegated to a ward tender, a green medical officer, or may be to an inexperienced practitioner, and an unsuccessful result is sometimes due to this, much to the patient's disappointment and surgeon's chagrin.

Personal supervision for three or four weeks is necessary, then it may be entrusted to attendants, who are to notify the surgeon on the occurrence of any pain about the wound.

The discharge of pus in a case which has been properly operated on is insignificant in comparison with the

often profuse and fetid discharge which comes from the branch sinuses of an incomplete operation. This is specially noticeable, and after a thorough operation, pus is remarkable by its absence, and also the wound soon becomes a healthy granulating ulcer. The fearful gash one sees after the proper operation on a complicated case of anal fistula reminds one of an amputation of the thigh. This is due to the thorough slitting up of all sinuses and crevices, the liberal trimming off of the edges, and the removal of the overhanging tabs, which swell (as the irritated gum does) and obstruct the free flow of the discharge. By so doing we have a shallow wound, all bottom and no top, and the rapidity with which these wounds heal under favorable conditions is surprising.

The solid packing of the wound in the first instance, compressing the vessels and thus arresting hæmorrhage, is allowed to remain to come away with the first motion of the bowels, which is to take place in three or four days. The curious treatment of removing the lint on the morning following the operation, I deem wrong, as too much and constant dressing I consider productive only of harm. If the flat wound gets flabby it may need the stimulating qualities of the usual remedies appropriate in such cases.

In the after-treatment it is usually sufficient to lay a light pledget of cotton on the wound, being on the look-out for new sinuses or crevices by running over the wound's surface with a probe.

If we would guarantee a cure, the operation must be properly done and subsequent treatment carefully attended to. In anal fistula dependent on stricture of the bowel dilatation of the stricture must be done to insure a permanent cure.

The blind internal variety of anal fistula is not uncommon, and is readily detected by an experienced hand, and by attention to the patient's history.

It is to this class of fistula that I would especially call your attention, baffling, as it does, physicians, and most surgeons, yet giving great pain and discomfort to the patient if allowed to go unrelieved, such a case being classed as an obscure case. The remedy consists in making it a complete fistula, and operating as stated.

The futility of attempting to cure all cases of fistula ani by caustics, or injections, as by the charlatans, may well be taken to task by reference to cases of this variety. It is the happy result in these obscure cases which is gratifying to the surgeon.

We may attempt the use of an injection or caustic in a fistulous track, if great objection is made to other means, but it is not serviceable, takes a long time, may be a year or more, and in general is ineffectual, as in the cases so treated by the order of Louis XIV.

From the appearance of a fistula, experience very often tells us without questioning the patient, that he has some lung lesion, which, if in an active advancing stage, would influence us against performing any operation, other than for the mere relief of pain — nothing radical.

If the lung affection is stationary a fair prospect of relief may be entertained by the elastic ligature, if the track is simple, or by the knife. Of course all these cases are not suitable for the latter means.

In all cases with rectal symptoms in which nothing pathological can be seen or felt to account satisfactorily for them, an enema should be administered, and bearing down of the lower bowel encouraged before an examination is made.

Such a procedure will often reward the surgeon by the detection of some lesion unattainable by other means, such as hæmorrhoids, prolapsus, certain tumors, etc.

The use of the anal speculum is limited, being used rarely by competent specialists in this department of surgery; in London they depend upon the information obtained by the "tactus eruditus" of a trained forefinger.

During a protracted service at St. Mark's (a hospital devoted specially to rectal diseases) I saw a rectal speculum used only once, and then at my request, so its employment is not as necessary an aid for a correct diagnosis as many imagine.

Through a simple incision the clot of blood in a case of external hæmorrhoids can be readily squeezed out, and oftentimes the severe, acute pain leaves as by magic.

In the operation for the cure of internal hæmorrhoids the ligature, clamp and cautery, crushing, and acids have each their advocates.

Every case of piles does not mean surgical interference, but it should receive a proper examination to determine what method of treatment is suitable.

The use of nitric acid or the acid nitrate of mercury or other caustics on the surface of a hæmorrhoid, even in the milder capillary form, is not to be relied on; the relief is not sure nor permanent, especially if the patient leads an active life, and its employment is well nigh discarded by those who were its warmest adherents. The injection by a subcutaneous syringe of an acid, like carbolic acid, or of a styptic, as solution of the persulphate of iron, into the substance of the pile has been followed in mild cases by a shriveling up of the pile, but its use is not advised as it is often painful, inefficient, and dangerous. Its use causes more inflammation than is desirable, a lengthy treatment with a doubtful result.

The recently advocated method of crushing, being about the same as the clamp without the cautery, does not promise any better results than are attainable by other and safer means.

The clamp and cautery, invented by Cusack, of Dublin, and improved by Mr. Henry Smith and others, has as great a reputation as facts warrant, and is suitable chiefly for slight cases. To hope for a good result the iron should be heated to a *dull red heat*, and applied over the *whole* cut surface so as to seal all the vessels completely.

The operation for prolapsus by the clamp and cautery is exactly the same as for hæmorrhoids, though it is generally supposed to be different.

Galvano puncture, producing interstitial canterization, has been lauded by a few, but its use is not sure, is accompanied with great pain, inflammation, abscesses, and slow recovery.

The use of the ligature in the operation for hæmorrhoids in aggravated cases is the safest, surest, and best method for their obliteration, and has the most decided testimony in its favor for facility, efficiency, and safety. The advocates of the clamp and cautery attribute to the ligature greater liability to tetanus, pyæmia, and secondary hæmorrhage, but a well-known surgeon told me that in fifteen hundred cases of the employment of the ligature he lost but one by pyæmia, and in his whole experience had seen but two die of tetanus, and then its appearance could be attributed to an extraneous cause. The liability to secondary hæm-

orrhage by the ligature is certainly less than after the separation of the escar after the cautery. Pyæmia, ulceration of the bowel, and fistula follow the use of the clamp and cautery quite as often as the ligature. The operation by the ligature, as done here, namely, transfixion with a double thread and tying each way, has always appeared to me a curious one, and one which does not have a true anatomical justification, and I think the pile is less thoroughly removed, and more likely to return than if Salmon's operation is employed. This consists in seizing the pile with a vulsellum, cutting from the white mark which is seen where the skin and mucous membrane meet with strong scissors parallel to the axis of the bowel, to a varying distance up the gut, then applying a single ligature which will be horizontal to the axis of the gut at the uppermost limit of the cut. By this means the larger vessels, which in the main come from above and supply the pile, are completely isolated. The vessels lie just beneath the mucous membrane, and are securely tied if the ligature is placed well at the bottom of the groove. If the operation is properly done return of the disease is rare, but it may return if the surface only of the pile is removed.

It certainly is a sensible operation, and has a sound anatomical justification from the disposition of the rectal vessels in the lower part of the bowel, and, moreover, there is less destruction of tissue than by other means.

Partial prolapse of the bowel, which is often connected with or mistaken for hæmorrhoids, may be cured by the ligature or the clamp and cautery, the operation being the same as for piles, but true prolapse in the adult involving the whole calibre of the bowel is best treated by the actual cautery at a dull red heat. The number of the longitudinal scores on the prolapsed bowel should depend on its extent, but we should not omit to apply the hot iron in two or three places at the verge so as to get a contraction of that end of the bowel.

The treatment in cases of fissure does not consist solely of an incision through the sphincteric fibres, as suggested by Boyer, or through the mucous membrane, as maintained by Syne, or forcible dilatation of the sphincter ani, as suggested by Recamier, and later by Van Buren, but can very often be soundly and readily healed by appropriate medical treatment, — a laxative and an ointment.

Sometimes nothing short of an operation is effectual; this is specially the case when a polypoid growth hangs down from above into the fissure, as it not unfrequently does. The cases of fissure not ordinarily cured by the medical or surgical treatment stated are those in which this papilla-like body has been left, and its destruction is required before the fissure will heal soundly.

Some notes on the surgical treatment of the remaining rectal affections will be considered in a subsequent communication.

RECENT PROGRESS IN OBSTETRICS.

BY W. L. RICHARDSON, M. D.

THE INDUCTION OF ABORTION AS A THERAPEUTIC MEASURE.

IN an admirable paper, read before the Obstetrical Society of London,¹ Dr. Wm. O. Priestley states briefly the circumstances which would justify the induction of an abortion as a therapeutic measure. The paper dealt only with the artificial termination of pregnancy at an early stage. The pathological reasons adduced, as justifying the induction of abortion, were as follows: (1.) Such narrowing or deformity of the female pelvis as would absolutely preclude the birth of a living child. If the largest diameter of the pelvis is less than two and three fourths inches it is known that no living child can at full term be delivered. (2.) When the genital canals are so narrowed by the presence of tumors, cicatrices, or of malignant disease that a living child cannot pass through. The force of this rule is being constantly weakened by the success that now follows the use of antiseptic methods in abdominal section. Great care must also be exercised in deciding what obstacles are permanent and what ones can themselves be removed.

The next set of reasons were based upon different grounds. They included (a) diseases which, being caused by the pregnancy, become dangerous to the life of the mother, and (b) the complication of pregnancy with diseases which, when so combined, would become a source of danger. Under the first head he mentioned: (1.) Obstinate vomiting, depending on pregnancy, whenever the patient's strength is so reduced that a fatal result is anticipated if relief cannot be afforded. (2.) In eclampsia, occurring during early pregnancy, with or without albuminuria, where the attacks are so frequent and severe as to imperil the life of the patient. (3.) In some instances of irreducible retroversion or flexion of the uterus. The mere existence of this form of displacement and the impossibility of immediately reducing it does not necessarily call for the induction of abortion, but only when it gives rise to symptoms which show that the patient's life is in danger. It must always be remembered that an adjustment often takes place spontaneously at the time of quickening, even after attempts at replacement have previously failed. (4.) In cases of severe and uncontrollable hæmorrhage which threatens the life of the patient.

Under the second head the writer alluded to those cases in which in certain acute and chronic diseases the complication of pregnancy undoubtedly endangered the life of the patient, and in which the speedy termination of the pregnancy enhanced her chances of recovery. This rule included cases of acute dropsy, in which the patient was brought into a dangerous state of anæmia; cases of hæmorrhage from the bowels threatening to end in death; diseases of the heart attended with urgent and dangerous dyspnoea; severe chorea; mania depending on pregnancy. In cases of pregnancy complicated with ovarian tumors it has now been found to be compatible, both with the safety of the mother and her pregnancy, to remove the tumor during gestation. As a general rule Dr. Priestley claims that the induction of abortion is only a legiti-

Is accurate or not, that is the question;
Whether it is better for a man to suffer
The painful pains, and lasting scars of small pox,
Or to have him before the surgeon's hand,
And by being vaccinated, end them? Yes!
I do not say you, and I say we all
I do not say you, a thousand awful scars
I do not say you, or a consumption
Do you say, with a soft you now,
Or say you say, with the rounds
Is it not a question where?

¹ Transactions of Obstetrical Society of London, vol. xlix, 1880, p. 241.

mate operation when the life of the mother is so imperiled by the continuance of pregnancy that emptying the uterus presents itself as the only alternative to save the patient.

DRESSING FOR THE NAVEL.

In order to avoid the evil results which sometimes follow after the stump of the umbilical cord has dropped off, Dr. Dorhn advises¹ the use of the following antiseptic method of treatment. After having tied and cut the funis, the stump and the surrounding parts should be washed with a solution of carbolic acid (two and one half per cent.). A second carbolized ligature should then be applied inside of the first ligature, and the funis cut off with the ligature which had been previously tied. Some carbolized lint is applied over the stump, and a piece of sticking-plaster, about the size of the hand, is placed over the wound. This dressing is allowed to remain untouched until the seventh day; when removed the funis will be found either wholly or nearly separated. In the latter case it should be cut off with scissors.

CANCER OF THE CERVIX COMPLICATING PREGNANCY.

Dr. Richard Frommel (Berlin) gives² in detail the history of two cases of this complication which have occurred in his own practice. In both cases the malignant disease existed prior to the beginning of the pregnancy. The first case was terminated by the delivery by the Cesarean section. The child was made to breathe with difficulty and lived three months. After the extraction of the child the placenta and membranes were found to be adherent, and therefore were removed with considerable difficulty, and a drainage tube was introduced. The patient, however, died the second day after the operation. At the post-mortem examination hæmorrhagic peritonitis, Bright's disease of the kidney, and endocarditis were found. In the second case the child was dead; the presentation was transverse. The diseased tissue was removed, and the child was extracted by version. The malignant disease rapidly advanced, and although the patient bore the delivery of the child well, she died in about two weeks. Using these two cases as illustrations, Dr. Frommel adds that in cases in which pregnancy is complicated with malignant disease the choice of the operation to be performed should be made with direct reference to the degree of advance made by the carcinoma. If possible, the whole diseased tissue should be removed without any reference to the stage of the pregnancy or to the possible chances of its removal causing an abortion. He furthermore states that such removal is not likely to interfere with the course of the pregnancy. If, however, the carcinoma cannot be wholly removed, then, if the child is viable, Cesarean section, taking, of course, all possible antiseptic precautions, should be performed, it being understood that such an operation is done solely with reference to saving the life of the child. If the child is known to be dead the course that he followed in the second case is to be preferred.

As regards the diagnosis of malignant disease, the writer does not agree with Spiegelberg as to the value of the fixation of the mucous membrane to the underlying tissues, inasmuch as the investigations of Ruge and Vert have shown that such fixation is by no means

as common as Spiegelberg has claimed. The only reliable method of making a diagnosis is by a careful microscopic examination of a detached portion of the diseased tissue. When operative interference has been decided upon he advises the wedge-shaped excision of both lips of the os uteri, as recommended by Simon.

RUPTURE OF THE UTERUS.

Dr. R. P. M. Ames (Philadelphia) contributes³ a valuable paper on the subject of rupture of the uterus, based on a careful study of one hundred cases, the important details of which are given. The conclusions which he arrives at are:—

First. That rupture of the uterus is exceedingly rare, occurring only once in four thousand eight hundred and eighty-three cases.

Second. That the most frequent causes are, in their degree of frequency: deformed pelvis, more especially diminished antero-posterior diameter; disease of the uterine tissue; malformation and abnormal positions of the child; ergot and traumatism.

Third. That the symptoms are easily recognized, almost always present and generally very severe.

Fourth. That the prognosis is exceedingly variable, the greatest number of recoveries being one in three.

Fifth. That the greatest number of ruptures takes place from twenty-five to thirty years of age, and in the third and fourth pregnancies.

Sixth. That gastrotomy is the preferable mode of delivery, when the child has escaped into the abdominal cavity.

As regards the site at which the rupture takes place it is found that, when the rupture takes place during gestation it is nearly always in the fundus or its immediate vicinity; while, on the contrary, if it occurs during the labor, the seat of the rupture is in or about the neck or at least the inferior portion of the body.

DELIVERY IN NARROW PELVES.

Dr. Aug. F. Erich (Baltimore) gives⁴ the details of eighteen cases of delivery in women whose pelves were more or less narrowed. He then criticises them with a view of determining the relative value of the different operations which are recommended as applicable to such cases. The practitioner called to a case of dystocia due to a narrow pelvis finds himself required to make usually a prompt choice between the following means of delivery, namely: (1) long forceps; (2) podalic version; (3) craniotomy; (4) laparotomy; (5) gastro-hysterotomy or its modification, as suggested by Porro, gastro-hysterectomy. Having critically examined these different operations he gives the following conclusions:—

First. The propriety of the induction of premature labor is still questionable.

Second. That version, while it should never be the alternative of the forceps, should be tried in contracted flat pelves before resorting to craniotomy, but is worse than useless in a uniformly contracted pelvis after the forceps have failed.

Third. The forceps, when properly applied and used, are the safest means of delivery for both mother and child. After failure with them craniotomy is indicated, except in cases of narrow flat pelvis, where version should first be attempted.

Fourth. When there is not room enough for the

application of the forceps, and when the smallest diameter of the pelvis is less than two inches, laparoclytrotomy is indicated. . . . The forceps should always be used whenever the smallest diameter of the pelvis seems to be somewhere above two inches.

Fifth. In cases of rupture of the uterus where the child has escaped into the abdominal cavity, and in cases of extensive carcinoma of the cervix, Porro's operation (gastro-hysterectomy) should be performed in the interest of the child.

Sixth. The unmodified Caesarean section (gastro-hysterotomy) has been superseded by Porro's operation, which meets all the indications with less danger to the mother.

DILATATION OF THE CERVIX UTERI.

In a recent lecture by Dr. Leopold Landau¹ (Berlin) attention is called to the value of tupelo tents in effecting dilatation of the cervix uteri. These tents are made from the root and stem of the *nyssa aquatica*. They expand much more uniformly than laminaria tents and their power of expansion is also greater than that of any other tent, while, at the same time, they produce an equal amount of softening and infiltration of the tissue of the cervix. They are free from any tendency to produce septicæmia. A tupelo tent, having been properly inserted within the cervical canal, should be allowed to remain *in situ* for three or four hours when a larger one can be substituted for it. Dr. Landau has used these tents successfully for over two years without any unfavorable results.

Hospital Practice and Clinical Memoranda.

NEW YORK HOSPITAL.

CASES IN THE SERVICE OF DR. W. J. BULL, CHAMBERS STREET HOSPITAL, NEW YORK.

REPORTED BY DR. W. E. WRIGHT, HOUSE SURGEON.

COMPOUND INTERCAPSULAR FRACTURE OF RIGHT FEMUR WITH SIMPLE FRACTURE OF LEFT FEMUR AND LACERATED WOUND OF PERINEUM, WITH PROTRUSION OF INTESTINES.

W. W. B., aged forty-eight, United States porter, admitted December 11, 1880, 5.13 P. M. Patient brought to hospital by ambulance from — Street, where he had fallen three stories through a hatchway, striking on his feet astride of a barrel. On admission was in state of collapse. Examination revealed simple fracture of left femur at the middle, a lacerated wound in right gluteal fold, leading down to intercapsular fracture of right femur, and a rent in perineum, with protrusion of intestines, was also discovered. Intestines being uninjured were properly cleansed and replaced, and wounds washed with one to forty carbolic, and a large sponge, wet with one to forty carbolic, applied to rent in perineum. Very little hemorrhage. Fragments of fractured bones held in apposition by means of sand bags. Bladder found to be intact.

Ordered hot-air bath, Magendie's Solution, six drops, hypodermically, and one drachm ether hypodermically. Ether repeated every ten minutes. Patient could not be aroused from state of collapse, and died December 14th, 7.4 P. M.

¹ *Verh. d. Berl. Ges. f. Geburtsh. u. Gynæc.*, 1877.

Autopsy revealed simple transverse fracture of left femur; an intercapsular fracture of right femur communicating with air by means of a lacerated wound extending from tuberosity of right ischium to middle of descending ramus of right os pubis; a rent in perineum beginning at scrotal junction and extending back through anus to coccyx; a rent in anterior wall of rectum extending upwards four inches from margin of anus.

STRYCHNIA POISONING TREATED WITH CANNABIS INDICA AND CHLORAL HYDRATE.

George H., aged eighteen, German, in the United States two weeks, admitted November 25, 1881, 11.30 A. M. Brought to hospital by ambulance, having been found lying on the sidewalk, where he had fallen. Complained of feeling "weak in legs." On arriving at hospital he told ambulance surgeon that he had taken strychnine, "about as much as could be placed on a silver quarter." He had bought the drug in France, and had taken it in a fig about one half hour before arrival of ambulance.

On admission, pulse, respiration, and temperature normal; pupils also normal; legs somewhat rigid; fingers and forearms quite strongly flexed. As soon as patient was placed in bed he had a slight convulsion. Head drawn back, jaws fixed, fingers and forearms flexed, and legs and body very rigid. As soon as muscles had relaxed administered thirty grains sulphate zinc with large quantity of warm water. Immediately after swallowing emetic patient had a most violent convulsion; jaws firmly closed, muscles of face and neck very rigid; body arched, resting upon occiput and heels; muscles of abdomen very hard and tense; respiration ceased entirely; hands clenched, and arms and forearms strongly flexed and adducted; Face greatly cyanosed; eyes blood-shot, with dilated pupils; no radial pulse.

During spasm administered twelve drops Magendie and three grains extract cannabis indica hypodermically, artificial respiration being kept up. Spasm lasted one and one half minutes, when muscles relaxed, and emesis took place; vomiting encouraged by administering warm water until stomach was well emptied. As soon as vomiting had ceased, twenty-four grains chloral hydrate were administered by the mouth. Patient fell into light slumber. Slept quietly for three hours, when he awoke complaining only of a feeling of lameness and soreness in muscles over entire body. Legs still quite rigid. Administered fifteen grains chloral hydrate, after which patient slept quietly the rest of afternoon and night, and awoke the next morning feeling well, aside from slight headache and muscular pain.

Abscess formed at point of injection of cannabis indica. Patient was discharged four days after admission. If statement of patient is to be believed he took at least five grains of strychnia.

OPIUM POISONING TREATED WITH ATROPIA.

Mrs. B., aged thirty, married, domestic. Admitted January 18, 1881, 6.30 P. M. Patient brought to hospital by ambulance from — Precinct Station House. Had taken, with suicidal intent, one half ounce laudanum one half hour before admission. Patient in very bad general condition, showing a life of dissipation. On admission very stupid and aroused with great difficulty. Pupils contracted to pin points, and could not

be made to respond; respiration 12; pulse 100, full; temperature normal.

Washed out stomach thoroughly with stomach-pump. Administered one twenty-fourth grain atropia hypodermically, and ordered patient to be kept awake by walking and flagellation. In spite of all efforts patient became more and more stupid. Half past seven p. m., respiration 7; pulse 120; pupils minutely contracted. Administered one twelfth grain atropia hypodermically. Ordered electricity with flagellation. Half past eight p. m., respiration 6; pulse 120, very irregular; almost complete anaesthesia; conjunctivæ and soles of feet alone sensitive; pupils minutely contracted; face very pale; temperature 100° F. Administered one twelfth grain sulphate of atropia hypodermically; electricity continued. Nine p. m. Anaesthesia of conjunctivæ; respiration 6; pulse 120; pupils still minutely contracted. Administered one twelfth grain atropine hypodermically. Ten p. m. Respiration 4; pulse 120, very feeble; perfectly comatose; complete anaesthesia; no response of muscles to current; temperature 101° F. Administered one sixth grain atropine hypodermically. Eleven p. m. Respiration 6; pulse 140, but regular; pupils somewhat dilated, and respond feebly; face and neck flushed; conjunctivæ and soles of feet sensitive; muscles respond well to current. Half past eleven p. m. Respiration 9; pulse 120, soft and regular; pupils of nearly normal size; surface very cold. Ordered hot-air bath. Twelve m. Sensation over entire body; respiration 11; pulse 120.

January 19th, 12.30 A. M. Respiration 16; pulse 110, regular, and no longer of bounding character; pupils normal in size and reaction. Patient perfectly conscious. Sat up in bed with great difficulty, and asked to be walked about room. Patient talks thickly, and articulates with great difficulty. On being taken from bed by assistants patient could not stand, and with great difficulty could she lift her foot from the floor. Is still very stupid, but is easily aroused. Drank a cup of black coffee; stomach would not retain it, and act of vomiting did much to arouse patient. Two A. M. Respiration 16; pulse 110; temperature 100° F. Patient is kept awake by nurse; articulates more distinctly and with less difficulty; paralysis disappearing; retains strong coffee. Nine A. M. Pulse 100; respiration 20; temperature 100° F.; articulation rather difficult, but distinct; complains of pain in head and stomach; pupils normal; mouth and throat very dry; lips covered with bloody crusts. Drinks much milk.

From this date patient rapidly recovered, but for several days suffered greatly from neuralgia; pains in different parts of body, but mostly in face and neck.

It will be seen in the above case that not until eleven twenty-fourths of a grain of atropia were administered was there any effect obtained from the atropia, and that a very prompt effect followed the giving of the last sixth of a grain.

— Tobacco is prohibited to the students of Oberlin College, Girard College, and the Naval School at Annapolis. A similar rule has been recommended for West Point by the board of visitors. At Cornell University nearly all the students have voluntarily signed a pledge of abstinence.

— A petition from the British medical men in Rome in favor of vivisection has been presented to the House of Commons by Mr. J. C. Campbell.

Reports of Societies.

PROCEEDINGS OF THE NORFOLK DISTRICT MEDICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

SEA-AIR AND SEA-BATHING.

DECEMBER 28, 1880. At a meeting held on this date DR. T. H. DEARING read a paper on Sea-Air and Sea-Bathing, which were considered under the following heads:—

(1.) Anatomy of the skin, its physiological action, especially in relation to absorption, regulating temperature of the body, and influence upon the nerve centres.

(2.) The danger that might arise from free absorption of salt from the water, the benefits of baths as vehicles of temperature, and the relation of temperature to the combustion processes going on in the body.

(3.) Ultimate results of hot and cold bathing.

(4.) Two groups of the chronic sick, as to bathing, one, with systems capable of strong reaction, the other not.

(5.) Difference in temperature of water at the different beaches, the kind of baths available, and the indications requiring the several kinds.

(6.) Customs as to bathing at the various beaches, the precautions necessary, and the extent to which it may be carried.

Temperature of air, time of tide, time of eating, and means for producing reaction.

(7.) What children and old people may be benefited, and kinds of bathing suits.

(8.) Danger of bathing in acute diseases and during menstrual periods.

(9.) The chronic diseases benefited, cases of delayed or rapid growth of the young, also, sea-shore localities in which asthma is benefited.

(10.) Atmosphere at the shore, comparison with mountain air, with what elements impregnated, and the effect upon those who breathe it.

(11.) Cottage life at the sea-shore, an important phase of social life in summer, and necessity for children during vacation.

(12.) The family physician should be able to indicate proper places, time for departure and return, and give proper rules for guidance of their patrons while at these places.

DR. A. H. NICHOLS said that he was able to confirm from his experience what Dr. Dearing had said, but there were one or two points he would like to speak of further on. People in Boston say they live by the sea, and must go to the mountains for change of air, but they are really nine miles away from the sea, and unless in a storm they lose the ozone and iodine of the sea-air. He had made experiments at Rye Beach as to the summer temperature of the water and found that even a difference of one half a degree was perceptible. He was unable to account for the differences of temperature in salt water, unless from the influence of the gulf stream. In selecting a sea-shore residence care should be taken to see that the atmosphere contains the desirable elements. He cited Swampscott as being objectionable from its proximity to flats which stood exposed at low water.

MEDICAL EXPERT TESTIMONY.

DR. WALTER CHANNING then read a paper on Medical Expert Testimony, published in this number of the JOURNAL.

In the discussion which ensued, DR. HENRY A. MARTIN spoke against the appointment of the expert by the court. He thought that expert testimony was too apt to be confined to specialists; in his opinion, in most cases the general practitioner was quite as competent a witness as the specialist.

DR. BENJAMIN CUSHING remarked that while he agreed with the reader as to the present bad system of expert testimony, he was not satisfied with the proposed law quoted from Dr. Draper.

The president of the Massachusetts Medical Society, DR. H. W. WILLIAMS, being called upon as having already served on a committee on expert testimony, said that the American Academy of Arts and Sciences had coöperated with two or three of the medical societies in bringing the subject to the attention of a former legislature. It had seemed desirable that change should be made in the present method by which incompetent persons were often placed on the witness stand with no other qualification as experts than their own assertion. If these were plausible and audacious, and especially if long experience as venal witnesses had made them skillful in testifying, they were often able to impress a jury more than a really qualified man who had not equal facility in stating his opinions. The abuse was not one affecting merely our profession, but existed in all cases where men of science were called on for opinions as to facts laid before them; instances being common where a directly opposite explanation is given to the facts by scientific men employed by one side and the other, who cannot avoid partisan bias.

If one or more experts appointed by the court, or selected by the opposing counsel with the approval of the court, should hear the scientific evidence and give their interpretation and estimate of its value with their reasons therefor, if required, such testimony, being regarded as impartial, would have more weight than that of others; and though it would not preclude the calling of additional expert witnesses, it would tend to limit their number and influence. It would also make such other witnesses more cautious as to their testimony, and bring to light much which is now often purposely kept back by evasions which would be detected and exposed by an expert having the requisite knowledge of the subject.

DR. F. S. BILLINGS, veterinarian, who was present, said:—

Veterinary medical science occupies a position somewhat to be compared to that of medical science some three hundred years ago. The very name Veterinary Surgeon is a misnomer, there being very little resort to surgical operations in the practice. So far as the duties of the veterinarian extend to expert testimony in our courts it may be said to be most unsatisfactory. There seems to be no distinction made between the veritable quack, or empiric, and the educated man from the best schools. All are assumed to be doctors and the testimony of the one seems to be held equally valuable to that of the others. Again, the law seems to have very singular ideas of the value of true expert testimony. Like a juryman, it is assumed that the less we know about the particulars of the case in point the more valuable our testimony. Instead of allowing experts to hear the testi-

mony of witness before being called up, we are summoned in, and, although utterly uninformed of everything except the merest outlines of the case, we are at once called upon to give our opinions, before the main witnesses are called upon. Frequently we are so unceremoniously summoned as scarcely to know what the case is about before being called upon the stand. The absurd nonsense of looking upon the testimony of a veritable quack, although he may treat diseased animals, from the same standpoint as an educated man is a disgrace to an intelligent community.

MARCH 22, 1881. DR. E. G. WEST reported a case of Epithelioma of the Conjunctiva Bulbi, with microscopic specimens of which the following is a synopsis:

EPITHELIOMA OF THE CONJUNCTIVA BULBI.

Mr. Elliott is seventy-six years old, of good health and rather fleshy. He retired from business in the summer of 1879, and at this time first noticed two small white nodules in the external angle of the left eye, about the size of the head of a pin. These were mistaken for fleshy particles. By the summer of 1880 they had increased in size and others were added, and blood-vessels radiated from them. For two months preceding the 17th of September the growth was very rapid, becoming two thirds the size of the cornea, and encroaching on the latter one fifteenth of an inch. The discharge from the eye was creamy and considerable, but there was no pain. In consultation with Dr. Williams, it was decided to try to snip it off, inasmuch as most if not all these growths originate in the conjunctiva. During the operation the growth was found to be very brittle, but it was thoroughly removed and examined and found to be an epithelioma. The wound did not heal well and by four weeks after the operation the whole base was covered with little nodules. Eight weeks after the operation the mass had become even larger than it was before, and two deep pockets had formed, where the growth had extended under the conjunctiva, which would fill up with excretions and then discharge. After seeing Dr. Williams again, Dr. Wadsworth was seen and advised a total eunecleation, for the conjunctiva had been all removed in the first operation and therefore the growth must now be on the sclera, and so it could not be thoroughly removed without opening the cavity of the eye. That this opinion was correct was afterwards shown by microscopic examination. Removal of the outer half of the eye was rejected since there was no certainty how far the growth had gone, and the wearing of a glass eye might cause it to reappear. It was removed on December 4th, and since that time (four months) there has been no return, and he now has only a slight discharge from the eye.

The interesting points of the case are: the rarity of the disease, situated as it was; the great danger of its being overlooked, as it was in this case, when it is in that stage where it is most amenable to treatment, for this is the history of the majority of the cases on record; and the third point is its rapid return, being about as large in four weeks after the operation as it was before. The operation seeming only to stimulate the growth to greater activity.

DR. C. E. WING then read a paper on Unnecessary Surgical Operations in the Treatment of the Diseases of Women, published in a former number of the JOURNAL.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, M. D., SECRETARY.

MARCH 7, 1881. DR. G. W. GAY read a paper upon OTIS'S OPERATION FOR STRICTURE OF THE URETHRA, which is printed upon page 3 of this number of the JOURNAL.

DR. POST thought that the reader's experience was not very different from that of Mr. Berkeley Hill, who had taken pains to follow out Dr. Otis's ideas in a number of cases after Dr. Otis's personal instructions. He had found internal urethrotomy followed by serious consequences in a large proportion of cases, altogether too large to justify the operation for trivial causes, and his results were successful in but a small proportion of his operations. These cases were made the subject of a clinical lecture by Mr. Hill, which was answered by Dr. Otis, who claimed that the division of the stricture was not thoroughly done and needed to be repeated, and was inclined to make light of the complications. This lecture of Mr. Hill and his own answer Dr. Otis incorporated in his book. Certainly in the cases just reported the consequences of the operation were sufficiently alarming to make one cautious in its repetition.

DR. WATERMAN doubted whether the freedom from contraction of strictures after Dr. Otis's operation is as entire as the inventor claims. He himself would always prefer dilatation with sounds and overdistention with these if found of advantage.

DR. C. H. WILLIAMS remarked that oculists experienced difficulties in the treatment of strictures of the lachrymal duct very similar to those met with by surgeons in urethral stricture. The practice formerly was to incise these strictures with a probe-pointed bistoury, and afterwards to try to keep them open while healing by the passage of probes. It has finally become evident, however, that this procedure, far from producing a cure, often results in a closer stricture than before, and the best practice now seems to be to dilate such cases slowly by means of graduated probes.

DR. INGALLS said that few of these cases were followed up long enough after the operation to give valuable testimony as to the amount of success to be expected after the various methods of operating. He thought gradual dilatation the proper method of treatment for most of these cases. Especially would he avoid the Holt's dilator which he believes to be often productive of much harm with little hope of permanent good.

DR. GAY said that he did not wish to appear as an advocate for Otis's operation, although he thought that, when properly done, it might be useful in certain cases. He thought that Dr. Otis must be mistaken in some things mentioned in his book, as, for example, the location of stricture. It seemed to him that Sir Henry Thompson's researches proved conclusively that the majority of strictures were located in the deep portions of the urethra. Again, he could not believe that strictures were produced as easily as claimed by Dr. Otis, or that very slight contractions of the urethra caused as formidable an array of symptoms as he would have us believe.

DR. GAY spoke of two men whose strictures he had dilated ten years ago, and who had had no further trouble, as proving that this affection is not always as serious as is supposed by many.

PROCEEDINGS OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED meeting, first Thursday of April, H. O. MARCY, M. D. in the chair.

M. L. BROWN, M. D., read a paper entitled

THE GYNÆCIC AND OBSTETRIC USES OF CHLORAL HYDRATE.

He first gave a brief historical survey of the employment of this remedy since its introduction by Liebreich in June, 1869, and gave his adherence to the theory that its action is procured through conversion of the salt into chloroform when brought in contact with the alkaline reaction of the blood. He also emphasized the absence of disturbance of the sympathetic, — of the unfortunate after-effects which follow upon the action of opium. Proceeding to the subject proper of his paper, he accepted as a kind of text the declaration of Richardson: "Chloral hydrate produces muscular relaxation, which relaxation extends to the muscles of volition, and alike to the iris and muscular arterial system. Its action on the nervous system is primarily on the sympathetic ganglia, afterwards on the cerebrum, and finally upon the heart."

First of all was asserted the power which the drug possesses, in preëminent degree, to antagonize and control all irregular, excessive, and abnormal muscular contraction, whether it be the spasmodic action of uterine fibres in dysmenorrhœa, uterine colic, exceptionally painful labor, or, again, in traumatic tetanus. Such property makes it especially valuable in obstetric and gynæcological practice. The reader illustrated by giving the points of a case previously reported in the JOURNAL. In a second case recalled, the patient came temporarily under his care during an attack of dysmenorrhœa which had been in progress several days. Chloral hydrate speedily relieved spasm and consequent suffering, and menstruation proceeded without further difficulty. Still again, a patient in her third confinement suffered so severely that a chloral hydrate mixture was ordered, but the birth was accomplished before it could be procured. Soon after parturition extreme after-pains set in, although the os uteri and vagina were in normal condition. Twenty grains were administered, and this, soon repeated, afforded temporary relief; but occasional recourse to the same was required for two days longer, to subdue the constantly recurring spasmodic pain. Good recovery.

In dystocia from irregular uterine contraction, or when contraction is continuous, as in the so-called uterine tetanus, in spasmodic stricture of the os externum, and in hour-glass contraction, in these, and allied conditions due to spasm, and not to organic changes, chloral hydrate may be expected to afford speedy and complete relief, and will be found superior to bleeding, tepid baths, opiates, etc., etc.

Still again, the asserted power of chloral hydrate to prevent coagulation of the blood should render it a prophylactic of great value where might otherwise have occurred cardiac thrombosis or pulmonary embolism, — one of the most sudden and terrible accidents ever witnessed by the physician. The following summarized statement, based upon the writer's studies and observation, closed the paper: —

(1.) Chloral hydrate may be safely and efficiently

used in labor to relieve the pains of normal and of abnormal uterine contraction.

(2.) It suspends all undue reflex action and resulting pain of a tendency to retard labor.

(3.) Labor under its influence is of much shorter duration.

(4.) Its use with intent to relieve pain is most striking and satisfactory when pain is caused by abnormal and spasmodic muscular contraction.

In the discussion which followed, DR. WEEKS remarked that he had had a similarly favorable experience with the drug with Dr. Brown, but he was afraid of it. In a case of pneumonia in a child two grains had been ordered every two hours, up to a certain point. His directions were somewhat exceeded in respect of repetition and in the morning he found the child in collapse, which speedily ended in death. The doctor quoted from a tabulation of deaths attached to a series of papers published by Dr. Kane in the *Medical Record*, in support of his position. The uncertainty of the remedy had made him distrustful of it; at times it occasioned uncontrollable excitement, and again profound sleep. He still further gave the particulars of a case in which extreme collapse suddenly set in a short time after the completion of a severe labor. The patient required persistent measures of relief for four hours before she was brought round to a condition of commencing security. Nothing in the history or treatment of the case sufficiently accounted for this seizure, which had been wholly unexpected; but the doctor could not doubt if chloral hydrate had been used in the free manner recommended by the reader, and its sedative action added to the other adverse influences, the situation of his patient must have been much more critical.

DR. WARNER was not, for obvious reasons, familiar with the drug in obstetric practice, but he had used it considerably in medical and chronic gynecological cases, and regarded it with much less favor than formerly. He had also been annoyed by its occasional excitant influence.

DR. WEEKS again referred to the table of deaths previously noticed.

DR. WARNER made allusion to a physician, known to members of the society, who gave but three grains to a young child, and it never woke up.

DR. W. S. BROWN had observed the excitant influence complained of under circumstances of continuous employment, and thought it should seldom be thus used. Furthermore, we must use caution in our resort to the drug, as we would in resort to opium. There was the same danger of formation of habit. He related a striking case in point, which came to his knowledge soon after the introduction of the remedy into this country. Still, he agreed with the writer of the paper in its general scope. Chloral hydrate is the best antispasmodic we possess. If its therapeutic activity depends upon its conversion into chloroform in the blood, we can understand its uncertainty of operation, for chloroform is the most treacherous drug known to the profession.

DR. WARNER emphasized the difference in mode of death from toxic action of chloral hydrate and chloroform. Was accustomed to use chloroform frequently before he came to Boston; had never seen a death from it; when this seemed threatened it was customary to catch the patient up and hold him by the heels, with feet suspended.

DR. W. S. BROWN had learned not to keep chloral

hydrate in solution, especially when it is to be exposed to the sunlight; it should always be freshly prepared.

DR. WEEKS again urged his main objection to the drug in obstetric practice: we are always more or less exposed to a degree of collapse or to hemorrhage. Chloral is an uncertain remedy; we are never quite safe in its use, and in case of either accident remarked our patient is but poorly prepared for it, if she have been previously, for any time and to any extent, under the influence of this powerful depressant.

DR. M. L. BROWN, in reply to a statement of Dr. Warner that opium had equal antispasmodic virtues with chloral hydrate, insisted that with the latter we wholly escape the unfortunate after-effects which constitute a main objection to opium. He had formerly lived in a place where several deaths had resulted from hypodermic morphia, but he did not propose to abandon so invaluable a resource on this account. So with chloral hydrate; but we must use caution, and select our cases. He believed, however, that it was especially indicated and exceptionally safe where pain is present, and pain depending upon extensive reflex irritation accompanied by spasm.

DR. W. S. BROWN added that the presence of the excessive muscular action of parturition gave additional security.

DR. WARNER remarked upon Dr. Brown's recommendation of chloral hydrate where there is delay in labor because of rigidity, spasm, etc. Now nature will bring everything right if time is given. He considered the physician had no right to prescribe a powerful remedy, as is often done, and so perhaps hazard life, because of a little inconvenience to himself from waiting, or because of a slight ailment of which the patient is in haste to be relieved.

DR. FIELD, being asked by the chair for his opinion on the subject under discussion, confessed to a strong feeling of surprise and disappointment at the general distrust or disapproval expressed in regard to a remedy which he had come years since to regard as both indispensable and beneficent. He had not used chloral hydrate in parturition because, when he used anything, he had depended upon chloroform, and was perfectly satisfied with it. This powerful remedy, dangerous or uncertain elsewhere, was safe here. The researches of Simpson could discover no case of death or injury, either of mother or child, from its employment, both in private and in hospital obstetric practice; and Campbell, of Paris, had extended this investigation from 1869, where Simpson left it, to 1876, with like results. Believed chloral hydrate was particularly safe with the young, and should feel much at loss were he obliged to correct this opinion. Had repeatedly prescribed 5 gr. to a child under two years of age, as a sleeping draught, with orders to repeat once after one hour if effect were insufficient; and in conditions demanding such resource, and with proper selection of cases, he felt perfectly safe in following this course. Chloral hydrate, in toxic dose, is believed to act primarily upon the heart and subordinately on the respiratory centre, and the heart, at least, ought to be especially strong in the young subject. But there must be no grave interference, on the part of disease, with the respiratory centre when chloral is to be given, and he could understand how the remedy might act adversely in the pneumonia case reported by Dr. Weeks.

As respects the *modus operandi* of its action, he be-

lieved the theory of Liebreich had been disproved. As Gubler has pointed out, we cannot satisfactorily explain the action of chloral hydrate through its supposed conversion into chloroform, for, first, the quantity of chloroform resulting from a safe medicinal dose of chloral hydrate would be too small to produce any appreciable influence; again, the action of the remedy is not anæsthetic but soporific, is not promptly set up and speedily over with, as in case of chloroform, but is rather slow in inception and of continuance for many hours. Had always acted upon a principle, which he emphatically enunciated in his teachings, that a sufficient dose of chloral hydrate should be given to produce positive physiological effect. To an adult, give 15, 20 or 30 gr. To trust to 5 or 10 gr. is mere trifling, and the remedy would be better let alone altogether. Had always felt great security in its use, and was not often disappointed in its effects; but had been careful to keep in mind certain *contra-indications*. Chloral hydrate should either be avoided or be given in greatly diminished quantity and with close watchfulness in conditions indicating marked hyperalkalinity of the blood, whether this be procured by a course of alkaline medicine or be the result of disease. Second, in decided asthenia of the heart, and, third (probably), in emphatic central congestion or inflammation. The doctor added, his only unfortunate experience in a ten years' use of the drug, and a free use, attended neglect of caution in respect of *contra-indications*; but this was before the profession was informed on this subject. A medicinal dose exhibited to a patient for some time previously under alkaline treatment for rheumatism, and who had also a weak heart, produced alarming symptoms, and such as for nearly an hour seemed seriously to threaten life.

Again, it is of the utmost importance that the chloral hydrate we use should be pure. Liebreich, within two or three years, had written a notable article in which he attributed a large proportion of all deaths reported from the use of his hypnotic to the employment of an impure salt. The statements of the variety and prevalence of impure specimens in the market—and particularly the American market—are well nigh appalling. But, fortunately, this evil has been in large measure corrected, and the careful physician should never be at a loss obtain pure hydrate of chloral. Dr. Field said, in conclusion, he should indorse, for the most part, the conclusions and observations of Dr. Brown, as presented in his paper.

Dr. NOURIS was then called upon to give his opinion out of his extended obstetric experience. Replied, he would make one point: had never used chloroform in parturition, but of late years had largely resorted to hydrate of chloral. Whereas formerly it had been his practice to sit round all night awaiting the slow motions of the patient, he now gave chloral hydrate; got through with the case more speedily, and went home, quite likely long before morning. His practice is to give 15 gr., and very often to repeat every fifteen minutes until the patient has taken one drachm in all; he generally adds bromide to the mixture in the ratio of one part of the latter to two of the chloral. He illustrated his remarks by reference to a case whose previous parturient experience had prepared him for a tedious labor of a day and a half or longer, but with whom the relaxing influence of the chloral was so marked that the child was born almost before he could get ready to receive it.

Dr. FIELD would add one remark to his previous

statement, and that had to do with the concentration of the mixture to be used. Was sure much mischief had been done by giving the salt in insufficient dilution. It must always be freely diluted (for example, one grain to one drachm); it is of necessity a bulky medicine, and there is no escape from this inconvenience. In some reports of deaths it was made quite evident that herein lay the secret of the mishap, although the reporter was apparently unconscious of the fact. Concentrated chloral hydrate is a dangerous remedy, even within the limits of therapeutical dose, and may kill as a massive dose of oxalic acid sometimes does, almost instantly, as by shock and paralysis of the heart.

Dr. CLARKE, after allusion to the exaggerated doses which were formerly advised and used soon after the introduction of the drug.—an error now corrected,—remarked that his experience with it at the time of and after delivery had been very satisfactory; and he had never seen any accident from it. Gave it with great relief for after-pains. Had been brought, however, to a considerable extent, to substitute croton chloral,—originally through the recommendation of an English physician. Likes it because it can be given in smaller dose, with less water, and it occasions less burning of mouth and throat. Of chloral hydrate is accustomed to give 10 to 15 gr., and repeat as occasion requires.

Dr. STODDARD had seen no bad effects from chloral in obstetric practice, but was accustomed to use it with much satisfaction. If prostration were to follow after delivery he should hesitate to attribute it to the remedy; as it may depend upon so many other causes and appears often with one who has not taken the drug.

Dr. FIELD added it had already occurred to him, in Dr. Weeks's case, that had chloral been given the alarming shock or collapse might have been mitigated or wholly absent. The patient was exhausted by her efforts; had she received chloral in proper quantity her efforts should have been much less severe, and she would have been better sustained under them.

Dr. STODDARD asked Dr. Field how he made consistent his statement that chloral did not owe its physiological action to its conversion into chloroform through the alkaline reaction of the blood, and his other assertion that hyperalkalinity of the blood constituted a *contraindication* to its use. Dr. FIELD acknowledged the apparent inconsistency; herein would appear an argument in favor of Dr. Liebreich's theory; but there are too many arguments against it. Did not attempt to explain, but reported as a clinical fact, established by repeated observation. It is possible, however, that the formation of chloroform, which doubtless takes place somewhere before the chloral is eliminated, may be so suddenly accomplished in the hyperalkaline blood as to present the whole body of resultant chloroform in an instant, as it were, and in such way as to overwhelm with toxic effect.

Upon call for the views of the Chair, Dr. MARCY replied he was in Berlin when Liebreich introduced his new remedy, had daily opportunities to witness its remarkable effects, and afterwards saw what was done in London with it. Dr. Mead in Dublin gave a mixture, in all containing one ounce of the salt, to a stout Irishman, a teaspoonful to be taken at a time and repeated as often as pleased; and the man took the whole of it. He slept four days and everything was tried to awaken him without avail; he then awoke of himself and suffered no further discomfort except the

he said he had been on a spree. From all this he believed the drug must be a safe one. Soon after getting home was called to a healthy-looking girl plunged in violent hysterical mania; gave her one drachm chloral in divided doses; she went to sleep; he thought her comfortable, but she never awoke. He felt at the time and had always since believed that the drug killed her and that he was himself, in a sense, *particeps criminis*. A most thorough autopsy could discover no lesion anywhere, all looked sound and healthy. Had since believed chloral should be most thoughtfully watched, if given at all.

Dr. CLARKE called attention to the antipyretic action of chloral, but the time allotted to the discussion had fully passed.

On call for instruments, etc., Dr. MAKEY showed certain surgical appliances, and first, an *antiseptic cloth*. This answered in principle to absorbent cotton, all oily matter being eliminated. It was impregnated with a mixture consisting of vaseline and paraffine, of each two parts, resin five parts, and pure carbolic acid crystals one part. After having tried several specimens of cloth, he had fixed upon the same variety he had formerly used for plaster bandages. It cost but five or six cents a yard.

He also showed specimens of *animal ligature*. Had discarded ox tendon, after trial, because it was too fatty, as might have been expected in a stall-fed animal. In catgut the fibres are not strictly parallel,—the ligature is likely to yield, and it becomes necessary to apply more than one. The desideratum was animal tendon presenting parallelism of fibres and free from fatty matter; and this he had found in the tendon of the caribou. The ligatures were carbolicized, especial attention being given to purity of carbolic acid. Society adjourned.

RHODE ISLAND MEDICAL SOCIETY.

THE seventieth annual meeting of the Rhode Island Medical Society was held in Providence, June 8th, the president, Dr. Charles O'Leary, in the chair. Stephen H. Mears, M. D., of Newport, Joseph C. Maranda, M. D., of Woonsocket, and Alvin H. Eccleston, M. D., of Charlestown, were elected Fellows.

The annual report of the treasurer, Dr. C. H. Leonard, exhibited an unexpended balance of \$316, of which surplus \$200 was by vote transferred to the printing fund.

The report of the trustees of the Fiske Fund was presented by Dr. C. W. Parsons. The trustees made no award on subjects proposed for 1881. The following subjects were proposed for the year 1882:—

(1.) Neuralgia: its Causes, Pathology, and Treatment, with special reference to Nerve Stretching and Nerve Section as a Method of Cure.

(3.) Is the General Disuse of Blood-Letting in accordance with Sound Physiological Principles as applied to the Treatment of Disease?

For the best essay on either subject worthy of a premium the trustees offer the sum of one hundred and fifty dollars on the usual conditions.

The committee on the library reported, through Dr. T. Newell, that the society's library is rapidly growing. The collection comprises 1600 volumes, exclusive of pamphlets and unbound journals.

Dr. Job Kenyon, from the committee on expert testimony, reported that a petition was presented to

the legislature in 1879, showing the disabilities under which physicians suffered, and asking that relief might be granted to witnesses when testifying as experts. The General Assembly, a few weeks since, passed an act giving additional fees to "witnesses summoned and testifying as experts in behalf of the State," but affording no relief in private cases. Dr. Garvin, of the committee, offered the following resolution, which was unanimously adopted:—

Resolved, That the Fellows of this society, in serving as witnesses for parties other than the State, refuse, both when summoned and while upon the stand, to give expert testimony without suitable additional compensation.

The committee also tried to secure an act giving courts power to summon any competent person to testify as an expert whenever there are obscure or contradictory facts in the case, precisely as is now done in cases where civil engineers disagree regarding boundary lines. This idea of regulating expert testimony was for some cause or other ignored by the legislature, though urged upon their attention as a matter of great importance.

An amendment to the by-laws was adopted by which the annual meeting will hereafter be held on the third Thursday instead of the second Wednesday in June. The quarterly meetings are to be held on the third Thursday of September, December, and March.

The following officers were elected for the year 1881-82: President, Charles O'Leary. First Vice-President, Job Kenyon. Second Vice-President, O. C. Wiggin. Recording Secretary, George D. Hersey. Corresponding Secretary, E. M. Harris. Treasurer, C. H. Leonard. Board of Censors, David King, Ariel Ballou, Otis Bullock, J. H. Eldridge, George P. Baker, J. W. C. Ely, Lloyd Morton, S. S. Keene. Publishing Committee, H. G. Miller, R. F. Noyes, G. W. Porter. Committee on the Library, I. Newell, H. G. Miller, G. D. Hersey, O. C. Wiggin, G. W. Porter.

The president, Dr. O'Leary, delivered the annual address, a carefully prepared essay on *The Use and Abuse of Hospitals and Medical Charities*.

Following adjournment, upwards of one hundred Fellows of the society, with invited guests, sat down to the annual dinner, which was bountifully served at the City Hotel.

—The Washington Training School for Nurses has, in a public commencement, just issued (May 21th) its certificate of qualifications to three nurse graduates. The exercises were well attended, and proved quite interesting, as, in addition to the usual addresses and forms by the officers of the school, extended remarks in favor of the school were made by General Eaton, commissioner of education, and the Hon. Dr. Loring, commissioner of agriculture. The school was organized in 1877, has no endowment, *no congressional appropriation*, but has quietly and effectively worked its way along. The Art Loan Exhibition, held for its benefit some weeks since, brought something less than one thousand dollars into its treasury. There have been a number of pupils in attendance since it was organized, but some have removed from the city. Bellevue Training School has taken two, and others have given up the idea of becoming nurses.

Recent Literature.

Medical Electricity: A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By ROBERTS BARTHOLOW. Philadelphia: Henry C. Lea's Son & Co. 1881. Pages xx, 262.

Professor Bartholow's reputation is a favorable recommendation to any book of which he may be the author. This treatise is, as its title claims, practical. Throughout the book care has been taken to give in detail the kind of electricity which would be of most value in treating any disease, and the method of applying the electricity; the size of the electrodes, the places where they should be put, whether moved about or held stationary, in what direction the current should flow, the strength of current most desirable, and the frequency of application, all these and other details, important for the proper use of the agent, are mentioned, so that the book is in truth a practical guide. No attempt has been made to describe diseases, but various groups of affections are considered together, where such an arrangement is possible, and the value of electricity as a remedial agent in those groups of affections is stated once simply and precisely, and necessary variations are then given. While the author evidently speaks from personal experience, no cases are given to load the book with unnecessary accounts of symptoms in individual cases. The introductory chapters on electro-physics and electro-physiology are short and concise, giving all the information really necessary for the intelligent use of electricity in the treatment of disease, not, of course, giving a complete explanation of electricity as a physical agent or power. Probably the law of Ohm, as briefly explained on page 38, and the definitions of the Weber, the Volt, the Farad, etc., would not be understood by one who had no previous knowledge upon the subject: the explanations are altogether too brief to be easily understood; but these terms are of comparatively little importance in electro-therapeutics, and this brevity does not mar the usefulness of the book.

A few of the claims put forward for electricity as a therapeutic agent seem to be rather too strongly stated. The author seems to claim rather too much for galvanism as a means of restraining hyperæmia and promoting absorption of the effusion following cerebral embolism. In considering spinal paralysis a descending stable current is recommended, to be passed from the neck to the sacrum; also if tender points exist on the spine, the positive pole should be placed on them; then it is said that the spinal nerve roots, having an intimate relation to the lesions, ought also to be included in the circuit, by lateral application of the cathode to each side, taking each nerve in turn, the anode resting on its point of origin. This is, perhaps, a point in treatment too often neglected. It is generally thought sufficient to apply the current along the spine alone.

In treating neuralgia frequent *seances*, two or three daily, are advised. In severe cases this is wise; the only difficulty would probably be found in the expense, unless a properly trained nurse could be employed.

In many instances a large number of cells is advised, as many as thirty, forty, or even sixty; and where advised a strong current is of advantage, but it should be remembered by the general practitioner that the battery used is Siemens and Halske, the cutaneous irritation

from which is much less than when ordinary portable batteries are used.

Electrolysis is treated briefly, excepting the electrolysis of aneurisms, which is more fully considered.

The chapter on galvano-cautery is principally taken up with description of the batteries and other instruments, no attempt being made to describe the surgical diseases in which its use is indicated, only a few affections being mentioned to give certain cautions, or to show the value of the cautery.

For simplicity, conciseness, and its practical character in many useful hints scattered through its pages, this work is one of the most valuable that has yet been contributed upon the medical uses of electricity.

S. G. W.

Imperfect Hearing and the Hygiene of the Ear, including Nervous Symptoms, Tinnitus Aurium, Aurai Vertigo, Diseases of the Vaso-Pharyngeal Membrane, Middle Ear, and Mastoid Region. With Home Instruction of the Deaf. By LAURENCE TRENBELL, M. D., Ph. G., etc., etc. Third Edition, with Illustrations. Philadelphia: J. B. Lippincott & Co. 1881. Pp. 147. 8vo.

This little book, the third edition of which now appears, is rather a series of monographs upon the different subjects enumerated in the title given above than a continuous treatise upon the diseases of the ear. In it the author shows a familiarity with the literature of the subjects upon which he has drawn very largely, and at the same time his own experience is given in numerous histories of cases. The studious practitioner will find food for thought in some of the suggestions of the author, even where it is impossible to agree with him, but the lack of continuity in the work and the large number of quotations do not seem to adapt it for general reading, for which its title would imply it was intended.

A Treatise on the Diseases of the Nervous System. By WILLIAM A. HAMMOND. Seventh Edition, rewritten, enlarged, and improved. New York: D. Appleton & Co. 1881. Pp. 929.

Dr. Hammond's work is well known, and the fact that a seventh edition is now issued, ten years after the appearance of the first, is sufficient evidence of its popularity.

One of the improvements in this edition is the omission of the chapter on insanity. Additions have been made to chapters on cerebral congestion, syphilis of the brain, spinal cord, and nerves, and new sections introduced on diseases of the sympathetic nervous system. Other additions are also noticed in other chapters.

S. G. W.

—The British Medical Association will hold its forty-ninth annual meeting at Ryde, Isle of Wight, on August 9th, 10th, 11th, and 12th, under the presidency of Mr. Benjamin Barrow, a local practitioner of eminence, much respected in the Association, and several times mayor of Ryde. The meeting will be opened, as usual, with a short service, at which Bishop McDougall, a member of the Association, will deliver the sermon. The address in medicine will be given by Dr. Bristowe, that in surgery by Mr. Jonathan Hutchinson.

Medical and Surgical Journal.

THURSDAY, JULY 7, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

TRAINING AND ATHLETIC EXERCISES.

ALTHOUGH, as we stated in our previous remarks on this subject in the last JOURNAL, it is our belief that an intelligent study of the physiological requirements of the individual athlete, as well as of the class, is very necessary for securing the advantages and avoiding the possible evils of the various exercises at present in vogue, such positive facts as have been collected in regard to the health of men taking part in university boat races show pretty conclusively that scarcely any injurious effects can be traced to such contests, even at a period when training was far less rational than at present. It might naturally be expected that a preparation extending over a considerable period and increasing gradually in severity would of itself make a selection of the fittest for the final test, and offer a better record than the spasmodic efforts of scratch races or of individual rivalries.

Dr. E. H. Bradford, of Boston, published in the *New York Sanitarian* for January, 1877, the results of his inquiries in respect to the health and longevity of members of the Harvard University crews between the year of the first university race in this country (1853) and 1870.

The report, based upon answers received from the men themselves or from friends, covers one hundred and eleven individuals. Of these ten were killed during the civil war. The sum of the actual life of the other one hundred and one at the time of investigation already exceeded the expectation of life at the time of graduation, calculated according to Farr's tables, by a small amount. Six deaths from consumption were returned, but in all of these men either an hereditary tendency or an irregular life was satisfactorily established. In reply to a query as to personal opinions on the point, only one of the correspondents considered himself to have been injured by rowing, and one other, with an hereditary tendency to consumption, the actual disease developing sometime after graduation, thought that he might have been. Bradford was unable to learn of any authentic cases of sudden exhaustion in university races.

These results coincide, as far as they go, with the prior investigations of Morgan in regard to university oarsmen in England. Morgan's inquiries covered a larger number of men than Bradford's, and also a somewhat longer series of years; they were very thorough, his final statements representing the labor of some three years. No case of heart disease fairly

attributable to rowing is recorded, and no case of sudden exhaustion.

The results of these inquiries do not support the theoretical forebodings of Dr. B. W. Richardsou, expressed in his *Diseases of Modern Life*. The whole subject is one for the proper appreciation of which, however, facts are essentially desirable. A methodical tabulation of the careers and longevity of race horses would not be unprofitable in this connection. Horses are not prone to dissipation, nor do they conceal or misrepresent unflattering passages in their lives. There have been cases of deaths of race horses during a race, and we recall one such from rupture of the heart. As a rule, however, they improve in every way during the active part of their careers, and many attain old age. Much instructive information may accrue from the expert professional supervision to which exercises in some college gymnasia are now subjected.

At present the practicing physician, when consulted as to the advisability of a given youth's engaging in athletic exercises, has, apart from a possible knowledge of the family idiosyncracies, but very unsatisfactory data on which to base his opinion.

In the mean time, that training and athletic competitions ward off far more disease than they produce cannot be doubted, and even if we were compelled to regard these exercises as a sort of modern Minotaur, demanding the annual sacrifice of a specific number of our youth, we are still inclined to think that the indirect advantage to the State at large would justify the tribute.

JOSEPH SKODA.

WE were able in last week's issue merely to mention the fact of the death of this remarkable man, so remarkable as a medical teacher and reformer of medical education as to merit a much more extended notice. And we are the more impelled to speak of him at length inasmuch as the torments of the gout compelled him, some ten years ago, to resign his chair in the university, and so, to a degree, effaced him from men's minds; moreover, his reputation does not rest upon his writings, for he published no book save his *Treatise on Percussion and Auscultation*. Thus many are ignorant of what manner of man he was, and of the part which he played in the advancement of medical science and education.

Joseph Skoda was born in Pilsen, Bohemia, in 1805, began his medical studies in Vienna in 1825, took his degree in 1831, and then returned to Bohemia to practice. A year or two later, however, we find him again in Vienna as assistant physician in the General Hospital, where, side by side with Rokitsansky and other earnest but less eminent workers, he devoted himself especially for a time to the study of thoracic disease, at the post-mortem table as well as at the bedside. He also gave successful private courses on diseases of the chest. The outcome of this study was his work on *Percussion and Auscultation* in 1839, which has run through six German editions and was translated into English in 1853. About this time a

special department for diseases of the chest was set aside for him in the hospital, and in 1846 he was chosen professor of clinical medicine, a position which he held until his enforced retirement in 1871.

Of the group of great men to whose labors the fame of the Vienna school is chiefly due, Oppolzer was the first to depart; two years ago he was followed by Rokitsansky; it is scarcely a year since the news of Hebra's death reached us; now Skoda has gone; and Hyrtl alone remains, living out his declining years quietly in Hungary, and enjoying the rest which he has so richly earned.

These were the men who spread the renown of the Vienna school throughout the civilized world; and who, between 1850 and 1860, turned the tide of Americans and English seeking to complete their medical education in Europe from the French to the Austrian capital.

Until the early part of this century the science of medicine scarcely existed. Tradition and authority were all powerful, smothering common sense, and encouraging the public to regard medicine—as the existence of “homœopathy and kindred delusions” shows that it is even now too prone to do—in the light of a mysterious sort of black art, in the exercise of which aptitude was of far more value than special and painful training. Members of the profession themselves either found or thought it necessary to assume a certain preternatural wisdom in dealing with their patients; and few men dared to look facts square in the face, acknowledging their ignorance and setting their feet resolutely in the narrow scientific path which alone leads to true knowledge. In no countries, perhaps, was this state of affairs more strongly marked than in Germany and Austria. The subdivision of the former into miserable petty despotisms, and the centralized autocracy of the latter, did not offer conditions favorable for vigorous and independent thought in any direction.

Now there was no one man in Germany who did more than Skoda toward the improvement of medicine in these respects. In a truly scientific spirit he sought to establish a fact, and then by the careful use of every means at his disposal to arrive at its true explanation, utterly rejecting all hypotheses, and refusing to theorize save on what seemed to his critical mind a reasonable basis of fact and observation. He appeared on the scene when the great discoveries of Laennec were fresh, and had opened infinite possibilities to men's minds. He subjected Laennec's doctrines to rigid analysis, and insisted that the deductions to be drawn from physical signs lead *directly* to physical conditions and only *indirectly* to diseases. It is true that we do not now subscribe to all the doctrines of Skoda,—his theory of consonance, for instance. But that is of little consequence compared with the main fact that his spirit and line of work were the true ones, and that, actuated by no motives of personal jealousy, at a time when undue respect for authority had not passed away, he did not hesitate, after painstaking preparation, to criticise the authority even of the highest.

A medical friend suggested to us, the other day, in conversation, that Skoda was to Germany much what the late Jacob Bigelow was to us Americans in calling attention to the inherent tendency of many diseases to spontaneous recovery. As to medication he was very skeptical, a natural reaction from the over-reliance on drugs of his predecessors.

It was Skoda who suggested to his friend and pupil, Hebra, that he should turn his attention to dermatology, and the results which followed this advice are known to all the world. It was Skoda whose hard, good sense contributed in no small degree to the abandonment of the Latin language as a vehicle for medical lectures in Vienna about 1848.

Our authority for these two statements is that of Hebra himself. There are doubtless many of our readers who remember hearing the great dermatologist praise the Latinity of Hildebrand, one of the old school of professors, whose attention was so absorbed in turning elegant sentences in the classic tongue as to lead him to forget that it was his mission to teach his hearers medicine, or, to use the familiar, pithy words of Hebra, “Der alte Hildebrand, der kummerte sich viel mehr schön Lateinisch zu reden als die reine Wahrheit zu sprechen.”

Skoda's independence is well illustrated by the following anecdote about him, which was current in Vienna. He was summoned to the empress in his professional capacity, and when he arrived at the palace objection was raised by the attendants to admitting him to her majesty's presence, on the ground that his coat was shabby or unsuitable; thereupon the professor simply said, “If her majesty desires to see my coat I will go home, but if she desires to see me she will see me as I am.” It is scarcely necessary to say that the doors were then thrown open.

Before closing we cannot forbear alluding to a touching incident which occurred at Rokitsansky's funeral. Skoda had himself lifted into his carriage to pay the last respects to his life-long friend, and at the grave exclaimed, “I cannot die, and yet is my pain no less than his.” He is now at last released, and our calling is the better for his having lived.

MEDICAL NOTES.

—From the medical point of view there is one thing which the recent sad and criminal calamity at Washington—the shooting of President Garfield—does emphasize, and that is the great importance of restraining those of ill-balanced minds, the insane, before they proclaim their disease by extreme acts. At present the expert is hooted at if he advises early restraint to anticipate mischief, and hooted at just as much if he raises his voice against society's cry for the protection sought in vengeance.

—A memorial address was delivered by President Porter, of Yale College, on Monday evening, June 27th, commemorative of the life of Dr. David P. Smith, late professor of surgery in the medical department of Yale College.

—The following is the subject for the Jacksonian Prize of the Royal College of Surgeons of England for the ensuing year, namely, Wounds and other Injuries of Nerves: their Symptoms, Pathology, and Treatment. For the present year it is the Pathology and Surgical Treatment of Diseases of the Hip-Joint.

—Dr. Heschl, the professor of pathological anatomy in the University of Vienna, died on May 27th, in the fifty-seventh year of his age. The cause of death was an affection of the lungs, from which he had suffered during several months. Dr. Heschl succeeded the celebrated Rokitsansky in the professorship but a few years ago.

—The arrangements for a temporary museum of pathology, etc., to be held during the approaching International Medical Congress, are reported as making satisfactory progress. All objects of medical and surgical novelty, relating to pathology or the illustration of disease, will be acceptable, but the *British Medical Journal* has been requested to direct the attention of the profession definitely to two or three points.

(1.) Arrangements will be made, in respect to some very rare diseases, or those of especial interest, to show groups of living patients. In this way it is proposed to illustrate the following rare diseases: Addison's disease; coincidence of gout and rheumatic arthritis; Charcot's joint-disease; myxedema; syphilitic bone disease in children; mollities ossium; primary muscular atrophy; rupture of large nerve-trunks; morphea; keloid of alibert; true leprosy; lupus erythematosus; xanthelasma.

(2.) The committee wish especially to borrow, both from private individuals and from hospitals, good pictorial illustrations of disease.

(3.) In addition to the special subjects to be illustrated, which have been mentioned in the museum circular, it is desired to comprise the following: specimens of vesical calculi of unusual character, or those which have been removed by unusual methods, more especially those for which Bigelow's operation has been performed. Also specimens of biliary calculi of large size which have been passed by the bowel or removed by operation.

—The Philadelphia daily press reports an application for a charter for another medical association by graduates of the diploma mills. The objects of this independent medical association are stated to be to promote the purposes and defend the rights of all medical schools which are conducted in the legal way, etc. The attorney-general objected to the granting of the charter on the ground that some of the incorporators were graduates of certain colleges whose charters have been recently forfeited. In reply it was stated that it was a mere social organization, gotten up by a number of physicians who were respectable and honorable men, and that, moreover, it made no difference who the incorporators were provided the objects of the association were good. The court held the matter under advisement.

—Mr. Horstall, in a letter addressed to the *Manchester Guardian*, arising out of a statement by Dr. Boddoo and Mr. Tuckett that "British heads are

smaller than British heads used to be," points out that the conditions under which the youth of the country are brought up in these days are such as to favor the development of a stunted race. No playgrounds, no public gymnasias, and an enforced resort to early drinking and smoking are the main factors at work, according to this authority, in the production of a general enfeeblement, unknown in the freer and robust times of old. And there is, as the *Lancet* points out, considerable truth in the argument. With all our endeavors at improved sanitation, there remains much to be done in the way of physical education, and the gospel of a healthy body which shall be capable of all the demands made upon it needs to be strenuously preached and acted upon in the interests of the nation. The mode of life of a great number of our urban population is the great evil of civilization. Deprived of fresh air and healthy exercise, combined often with an improper and an inadequate supply of food, and a consequent resort to artificial stimulants, such people are growing up under conditions which can only lead to one result, that of defective development. We sadly want in this matter the exercise of that common sense which has usually been regarded as the peculiar feature of the British character, but which in some matters is kept wholly in the background, and never asserts itself.

—Diphtheria is said to be epidemic at Ludington, Mich. One hundred and twenty children have died recently in a population of four thousand people. The schools are closed, and special policemen have been stationed at the houses where sickness exists, to prevent ingress and egress.

NEW YORK.

—At the last meeting of the County Medical Society before the summer recess, June 27th, the following papers were read: The Japanese Otacoustic Fan and other Aids to Hearing, by Dr. Samuel Sexton; Report on Quebracho in Dyspnea, by the Therapeutic Society; and The Private Care of the Insane, by Dr. Ralph L. Parsons. Dr. Sexton stated that the Japanese instrument mentioned had been used with considerable success in the deaf and dumb asylum at Tokio, and claimed that it was an improvement on the Rhodes telephone, although it was of service only for a distance of three feet. The fan is made of lacquered wood, and does not differ materially in construction from the audiphone, the principle of action being the same in the two appliances. In commenting upon Dr. Sexton's paper, Dr. O. D. Pomeroy, one of the most prominent otologists in the city, stated that no cases in which the hearing was improved by means of the audiphone had come under his notice, although he was one of the first practically to test its powers.

—A conference was held on the 28th between the members of the Board of Health and the new street-cleaning commissioner, Mr. Coleman, when there was a general interchange of opinions and suggestions, with especial reference to the problem of the separation of ashes and garbage in the tenement-house dis-

tricts, the dumping of ashes and street refuse in open lots, and the filling in of sunken lots and swamp grounds with ashes free from garbage and other unwholesome material. The members of the Health Board assured Mr. Coleman of their earnest coöperation with him, volunteering to aid him in any proper way that he might suggest, and the latter stated that he would be compelled for the present, at least, to continue the system which had been handed down to him by his predecessors, the street-cleaning bureau, until he had had time to perfect a better one.

— On the same day Governor Cornell gave a hearing to the chief, consulting, and resident engineers of the Croton Aqueduct, Messrs. Newton, Chesbrough, and Church, who visited Albany for the purpose of requesting the governor to sign the bill which recently passed the legislature providing for the construction of a new Croton aqueduct. Among the documents presented in favor of the bill was a letter from Mayor Grace, in the course of which he said, "The critical condition of the supply during the past winter is an admonition that measures to obtain an abundant addition to the supply cannot be longer delayed without imperiling the health and property of our citizens. . . . Having arrived at a period when the Croton Aqueduct, although still performing its functions with unceasing regularity, has become inadequate to meet the city's wants, it seems to be our duty to profit by the example set by its projectors and builders, and make commensurate provision for an abundant water supply for the future, and the necessity for such provision is urgent." The president of the Board of Health, Professor Chandler, also sent a letter strongly urging the governor to sign the bill. For many years, he stated, the citizens had suffered seriously from the inadequacy of the water supply. There was an abundance of water of unexceptionable quality in the Croton water-shed, but it could not be brought to the city in additional quantity because the present aqueduct was already taxed to its utmost capacity, which was less than one hundred million gallons per day. It was now impossible in most of the dwelling-houses to get water to the third floor, even in those provided with the most complete system of plumbing. As a consequence the closets were not properly flushed, the houses were permeated with sewer-gas, and there was a constantly increasing number of complaints of sickness and ill-health resulting from this cause. "The health officers of the city," he continued, "have viewed with increasing alarm this deficiency of water. No sanitary measures which they can devise are sufficient to prevent the evils which result from it. In my opinion the demand for an increased supply of water, and a large increase, which can only be secured by a new aqueduct, is imperative. No matter what the cost to the city, we must have for the health and comfort of our constantly increasing population a new aqueduct, nor can we afford to postpone the commencement of the work." The letter concluded as follows: "The recent report of Mr. Isaac Newton, the very competent engineer of the Croton Aqueduct, supported by the opinion of E. S. Chesbrough, the oldest and

most experienced hydraulic engineer in the country, carried conviction to my mind, and is in full accord with all that I have learned on the subject of water supply during the past twenty years, during which it has been a subject of study with me. I believe that this bill will accomplish in the most satisfactory manner all that is required in this direction, and I fail to detect anything in the bill, as amended and now before you, to which I can object either as an expert on water supply or as a citizen and tax-payer of New York."

— In view of the comparative scarceness of water, on account of the rapid increase of the population, as well as the enormous waste that is continually going on, it will undoubtedly be necessary to increase the number of water metres throughout the city, until an additional supply of water can be obtained by the construction of a new aqueduct. In a recent communication to the board of aldermen upon this subject, Mr. Herbert Thompson, Commissioner of Public Works, says, "I deem it proper to say that in the present condition of our water supply the compulsory use of water meters in certain classes of buildings, while generally unpopular, is an absolute necessity. A superabundance of supply and pressure of water in past years has produced habits of waste with consumers which can no longer be indulged without depriving a large part of the population of the necessary supply, and which can be suppressed or limited only by the use of meters. For many years past we have been receiving in the city all the water which the Croton Aqueduct can carry, and until additional conduits are completed we cannot receive more. In the mean time the supply must be so husbanded as to maintain an equitable distribution to the rapidly increasing population."

— A new charity of a somewhat novel character, the New York Medical Mission, has just been started in the densely populated lower portion of the city, the rooms of the mission being at No. 5 East Broadway. The plan of the institution is to give free medical treatment to all patients who are unable to pay for it, and by holding out this inducement to go to the mission rooms to obtain an opportunity for preaching and instruction among a class of individuals who could not otherwise be brought to attend religious services. Between half past nine and ten A. M. each day the names of all persons who desire medical treatment, but who are too ill to leave their homes, will be received, and at two P. M. there will be a short religious service, with music, after which the patients will be treated in the dispensary. While there will be no charge for medical attendance, patients will be expected to contribute such amounts as they can afford for the support of the mission. The fact that those too ill to come out will be treated in their own homes will furnish an opportunity, it is thought, for discovering whether charity is really needed or not in the families thus visited. The opening service was held at the mission on the 27th of June, when Dr. C. R. Agnew presided, and among those who took part in the exercises were Prof. Alfred C. Post, Dr. D. B.

McCarter, for many years a medical missionary in China and Japan, and the Rev. Mr. Constantine, of Smyrna. The medical superintendent will be Dr. George D. Dowhott, formerly in the British admiralty service, who is said to have been very successful in establishing medical missions similar to this in Liverpool and in Philadelphia.

Miscellany.

CRIMINAL ABORTION.

MR. EDITOR.—The report of the proceedings of the Suffolk District Medical Society, which appears in your issue of the 14th ult., contains an abstract of a paper by Dr. F. A. Harris entitled *A Case of Criminal Abortion, with Acquittal*. I suppose that Dr. Harris refers to a case in which I was called by the defense to testify as an expert, and that his remarks in regard to a certain medical witness are intended to apply to me. Upon the presumption, then, that this is the case, with your permission I wish to say a word in reply to some of the statements made by Dr. Harris. I should have done this sooner, but since I became aware of the publication of the paper in question I have not, until now, been able to command even the brief time required in taking this notice of it.

In regard to the question of the advisability of resorting to artificial delivery in cases of puerperal convulsions I shall have no argument with Dr. Harris. Fortunately, it is not left for either of us to decide, except in cases that come under our immediate observation. I said that "in dangerous cases which do not yield to other measures artificial delivery is demanded, and is the practice of the best obstetricians," and this I have no hesitation in repeating. If Dr. Harris desires to criticise this opinion, or any opinion that I have ever expressed, I have no objection to his so doing, and I shall have no controversy with him; but when he makes a statement of what he alleges to be facts having reference to me I shall insist upon a fair and truthful presentation of such facts.

Apparently, Dr. Harris would have it understood that I diagnosed a case of "eclampsia," upon the last statement,—"she was lying on her side, her knees drawn up, and hands clenched, and groaning." Such was not the case. The accused, upon whose statement Dr. Harris says I testified, gave a classical description of a typical case of puerperal convulsions, stating, among other things, in addition to the above, that the woman was unconscious; and that he so testified is indicated in the brief of his testimony taken by the prosecuting attorney. The defendant further stated that the woman had general convulsions. I submit, then, that his statement was not "a description of an ordinary labor pain."

The assertion of Dr. Harris that I said "that one could not perform venesection at first," grows out of my remark that "venesection is inadmissible in some cases." The statement which he puts in this form, "He should do leeching and cupping, not venesection," was preceded by the qualification, "In many cases."

Perhaps the quickest way to substantiate what I have said upon these points is to give a copy of the notes of my testimony upon them, taken by the assistant district attorney, who acted as the prosecuting officer,

together with his explanation of their meaning when their meaning is not perfectly obvious; the explanations being in brackets: "Treatment of eclampsia. Do something as soon as you can; let blood; best thing; can't perform venesection; leeches or cupping. [If you cannot perform venesection, employ leeching or cupping.] Almost always counter-irritation; quick application; hot iron; mustard; let blood; let no more. [Let no more than is necessary.] Relieve by ether; empty the uterus; kidney disease; albumen in urine; some of best authors say deliver at once. [That is, if relief is not obtained from blood-letting, anaesthetics, etc.] Empty the bladder; ether or chloroform should at once be given." Now, in view of this, which, so far as it goes, correctly represents my testimony upon the points mentioned, I submit that the statements of Dr. Harris are neither fair, nor just, nor truthful.

I did not state that "the disease"—puerperal convulsions—"was almost always fatal;" but I did say, "it is a very dangerous and fatal disease."

Dr. Harris says that I was "pressed" for the names of authors that advised artificial delivery. Such was not the case. I held in my hand a list of such authors, with Barnes at the head. I named him first, and before I had time to name another Dr. Harris spoke to the prosecuting officer, who immediately asked me if I was sure that Barnes advised this measure. I replied, embodying in my reply an extract from Barnes, which evidently did not suit the government, and the cross-examination was immediately turned upon another line. I could easily have read the other names contained in my list had I been asked or even allowed to do so. My testimony in regard to the wounds was that those that were wholly vaginal were probably made by some sharp instrument, and that the destruction of tissues in and about the *cervix uteri* might have resulted from lacerations caused by the expulsion of the fetus or by forcible manual attempts to remove it.

Dr. Harris says, "this expert testified that the fetus could not be got out by forcible means in an hour and a half." The only testimony to which this can refer was given in answer to a hypothetical question: "Suppose a woman to be five or six months pregnant and not in labor, could artificial delivery be begun and completed in an hour and a half?" I replied that I did not think it could; that I had made two attempts at about this period of pregnancy, one at five and the other at six months, and with the aid of an accomplished obstetrician in each case I had not been able to effect delivery in either, in that length of time.

Now in regard to Barnes, Dr. Harris says that this author "not only does not advise but protests against it (that is, artificial delivery) in the period before the eighth month in eclampsia," and he also made a statement substantially the same as this under oath.

In his lectures on *Obstetric Operations*, 1876, page 455, Barnes says: "Gestation may be divided arbitrarily into two parts. During the first part, terminating at six and one half or seven months, or at the end of one hundred and eighty or two hundred days, it is scarcely probable that a viable fetus will be expelled. To induce labor within this period is really to bring about abortion. It is, therefore, only done under the pressure of conditions that preclude waiting until the child is viable, and out of regard solely for the safety of the mother."

Page 456. "It will be convenient to enumerate first

those conditions which, in the interest of the mother, and disregarding the child, demand the interruption of gestation during the first part."

As one of these conditions he specifies "some cases of albuminuria, convulsions being present or apprehended."

Page 457. "My experience leads me to conclude that in cases of urgent disease there is more frequent occasion to regret having delayed the operation too long, than having had recourse to it too soon."

Page 462. "Take first the case of *convulsions*. It has been seen over and over again that the convulsions have ceased soon after the uterus has been emptied. Everything conspires to prove that the convulsions are due to conditions arising out of the pregnancy. What, then, more logical than to terminate the pregnancy as soon as possible? Yet experience suggests caution as to the mode of acting. In not a few cases the completion of labor has failed to put an end to the convulsions. In other cases death has followed labor, whether this have occurred spontaneously or have been induced. Is the unfortunate issue the consequence of procrastination in inducing labor, or of over haste of (or?) want of precaution in the mode of proceeding? I believe it is due sometimes to one cause and sometimes to the other."

Now in view of these distinct statements of Dr. Barnes it seems to me that Dr. Harris must acknowledge that Barnes does advise what Dr. Harris says he does not, and that Dr. Harris must stand convicted of ignorance or willful misrepresentation. I leave it for him to decide which.

One or two reflections and I shall be done. If the opinions I gave in this case were erroneous, they could have been successfully controverted by testimony in rebuttal. The government had all of one evening and night in which to procure witnesses to contradict my statements. I have good reason, I think, for believing that an instructor in obstetrics in Harvard University medical school was consulted about the matter. Why was not he called? Why was not the professor of obstetrics in the same school summoned? It would have given me great pleasure to have heard him testify upon the point in question. Why was not the other medical examiner of Suffolk County, who was placed upon the stand during the government's rebuttal to testify upon other matters, asked in regard to this one? Why, if my testimony was so "extraordinary," so wide of the truth, so prejudicial to the interests of justice and yet so easily dissipated by the slightest "puff of empty air," as Dr. Harris would seem to wish his hearers to believe, why was not a single witness produced to controvert, contradict, expose, and show it up in all of its villainous perjury?

J. B. TREADWELL.

Boston, May 19, 1881.

THE BOYLSTON PRIZE.

THE *British Medical Journal* contains the following:—

We learn with pleasure that the Boylston prize of three hundred dollars, offered for the best dissertation on Injuries of the Back without apparent Mechanical Lesion in their surgical and medico-legal aspects, has been awarded to Mr. Herbert Page of St. Mary's Hospital. As surgeon to the London and North-

Western Railway, Mr. Page has had considerable experience in the subject-matter of the essay, and has collected materials which were available for the subject announced. The subject of the second prize was the effects of drugs during their application on either nurses or nursing. From a communication we have received from Mr. Dolan of Halifax, it appears that he had forwarded a dissertation, of course under motto in the proper manner, for this prize, and has received in reply a communication from the secretary, informing him that the prize would have been awarded to his essay, as being the best dissertation on the subject of which it treats; it was, however, debarred from competition by its having been published, prior to their decision, in the *Practitioner* of February, 1881, and subsequent numbers, otherwise it would have received the prize. Mr. Dolan made this public in ignorance of the rule, which is, however, a very customary and usual one in the case of all prize essays.

DARWIN'S VIEWS ON VIVISECTION.

The following letter from Mr. Darwin in reply to a letter from Professor Hohngren, of Upsala, requesting his views on the right to make experiments on living animals in the interest of science, we copy from the *Popular Science Monthly*:—

Down, Beckenham, April 14, 1881.

DEAR SIR.—In answer to your courteous letter of April 7th, I have no objection to express my opinion with respect to the right of experimenting on living animals. I use this latter expression as more correct and comprehensive than that of vivisection. You are at liberty to make any use of this letter which you may think fit, but if published I should wish the whole to appear. I have all my life been a strong advocate for humanity to animals, and have done what I could in my writings to enforce this duty. Several years ago, when the agitation against physiologists commenced in England, it was asserted that inhumanity was here practiced, and useless suffering caused to animals; and I was led to think that it might be advisable to have an act of Parliament on the subject. I then took an active part in trying to get a bill passed, such as would have removed all just cause of complaint, and at the same time have left physiologists free to pursue their researches—a bill very different from the act which has since been passed. It is right to add that the investigation of the matter by a Royal Commission proved that the accusations made against our English physiologists were false. From all that I have heard, however, I fear that in some parts of Europe little regard is paid to the sufferings of animals, and if this be the case I should be glad to hear of legislation against inhumanity in any such country. On the other hand, I know that physiology cannot possibly progress except by means of experiments on living animals, and I feel the deepest conviction that he who retards the progress of physiology commits a crime against mankind. Any one who remembers, as I can, the state of this science half a century ago, must admit that it has made immense progress, and it is now progressing at an ever-increasing rate.

What improvements in medical practice may be directly attributed to physiological research is a question which can be properly discussed only by those

physiologists and medical practitioners who have studied the history of their subjects; but, as far as I can learn, the benefits are already great. However this may be, no one, unless he is grossly ignorant of what science has done for mankind, can entertain any doubt of the incalculable benefits which will hereafter be derived from physiology, not only by man, but by the lower animals. Look, for instance, at Pasteur's results in modifying the germs of the most malignant diseases, from which, as it so happens, animals will in the first place receive more relief than man. Let it be remembered how many lives and what a fearful amount of suffering have been saved by the knowledge gained of parasitic worms through the experiments of Virchow and others on living animals. In the future every one will be astonished at the ingratitude shown, at least in England, to these benefactors of mankind. As for myself, permit me to assure you that I honor, and shall always honor, every one who advances the noble science of physiology.

Dear sir, yours faithfully,

CHARLES DARWIN.

TO PROFESSOR HOLMGREN.

THE AMERICAN MEDICAL ASSOCIATION.

THE following extract from the *Medical Times and Gazette* shows all the space that periodical considers it necessary to devote to the American Medical Association:—

The thirty-second annual meeting of this body, held in May, 1881, at Richmond, Virginia, has, according to the *New York Medical Record* (May 14th), been attended only with a moderate amount of success, either as regards the numbers present or the importance of the subjects discussed. Singularly enough, the numbers of delegates from the South and Southwest were scanty, those from Pennsylvania being largely in excess of any other State. As was to be expected, from the well-known hospitality of the South, the meeting was socially a complete success. A committee has been appointed, with directions to report next year, with the view of converting the annual volume of Transactions (which no one ever reads) into a weekly journal. In his address on Obstetrics and Gynecology, Dr. Chadwick, of Boston, claims preëminence in this field at the present time for the United States; for although he believes that the beneficial results of surgical interference are by some exaggerated, yet, "taken all in all, close observation and study in most of the countries of Europe have confirmed me in the opinion that in obstetrics and gynecology America leads the world." England, he says, is fast losing its preëminence in this branch of medicine, for while America is publishing such important journals as the *American Journal of Obstetrics* and the *Transactions of the American Gynecological Society*, she has discontinued her solitary *Obstetrical Journal* for want of support. A heated discussion took place upon a motion that it should be "considered derogatory to the interests of the public and the honor of the profession for any physician or teacher to aid in any way the medical teaching or graduation of persons, knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine." This was warmly debated, and in the end an amendment by Dr. Gillings was carried, namely:

"It is not in accord with the interest of the public or the honor of the profession that any physician or teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with, the graduation of persons who they have good reason to believe intend to support and practice any exclusive and irregular system of medicine."

SEA-AIR AND INFANTILE DIARRHŒA.

THE Sea-Shore Home has just issued its Annual Report for 1880. Dr. Edward T. Williams, the physician in charge of the Home for several years, thus sums up his experience.

(1.) Sea-air is *not* an infallible cure for infantile diarrhœa. Some cases will die under the best management.

(2.) The vast majority of cases get well if removed early and properly fed and cared for.

(3.) After decided collapse and head symptoms come on, death is the rule, recovery the fortunate exception.

(4.) Bronchial and pulmonary complications are usually aggravated by the cold air.

(5.) Not a few cases are made worse by exposure in stormy weather and the cold nights of the last of August and September; at these times, both fires and extra clothing are needed, and some take cold in spite of them. Indeed, it has seemed to me that the autumnal diarrhœas are chiefly caused by cold, and are unsuited to the seaside.

FEEDING-BOTTLES.

IT is impossible to enforce too strongly the paramount importance of keeping the feeding-bottles of infants perfectly clean and sweet; so we give the following from a paper lately presented to the French Academy of Sciences. Several infants' feeding-bottles in use at a crèche in Paris, and having a fetid odor, were taken by Dr. M. Mesnil to the Municipal Laboratory for examination. M. Fauvel found that the milk remaining in all had a sickening smell, was acid, and half-coagulated; and on microscopic examination, the globules were deformed, and numerous very lively bacteria, along with some vibrios, were present. On cutting open the caoutchouc tube throughout its length coagulated milk with small organisms was met with; but a still more important fact was the presence in the nipple of a mass of vegetation of cryptogamic nature. Sown in whey, this developed considerably in a few days. A visitation of all the crèches was then arranged by the police and medical authorities, with the following result: Of thirty-one feeding-bottles examined in ten crèches, twenty-eight contained in the nipple, the caoutchouc tube, and in some cases in the glass bottle, vegetations of the kind indicated, as well as bacteria, etc. Several that had been washed carefully, and were considered ready for use, still contained these cryptogams. Two feeding-bottles in a very bad state were found to contain pus and blood-corpuscles; the children who had used them had injuries in the cavity of the mouth. It is thus probable that saliva enters the feeding-bottle, and its ferments are added to those of milk. The acidity of the milk is attributed by M.

Fauvel to the bacteria present. We do not suppose that there is anything new in all this, but the graphic description of the freely growing moulds, the very vivacious bacteria, and the more scarce vibrios that may be found in babies' feeding-bottles may impress

the minds of mothers and nurses more than any common-phrased injunctions. It might, however, really be useful to publish pictures of the world found in a drop of sour milk from a dirty feeding-bottle, to be hung up in every nursery. — *Medical Times and Gazette*.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 25, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2707 (no reports from Pittsburgh or Buffalo); 1299 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 834; diarrheal diseases 380, consumption 324, lung diseases 182, diphtheria and croup 152, scarlet fever 75, small-pox 41, measles 40, cerebro-spinal meningitis 38, typhoid fever 37, malarial fevers 33, whooping-cough 23, puerperal fever 14, erysipelas eight, typhus fever three. From *small-pox*, Philadelphia and Chicago 15, New York 10, Brooklyn one. From *measles*, New York 23, Baltimore and Cincinnati four, Philadelphia, Brooklyn, Chicago, Boston, New Orleans, District of Columbia, Milwaukee, Providence, and Worcester one. From *cerebro-spinal meningitis*, Chicago 12, New York 10, Philadelphia and Holyoke four, Milwaukee two, St. Louis, Cincinnati, District of Columbia, Haverhill, Waltham, and Woburn one. From *typhoid fever*, Chicago six, Philadelphia four, New York, Baltimore, Cincinnati, and Milwaukee three, St. Louis, District of Columbia, Charleston, Lowell, and Fall River two, Brooklyn, Boston, Providence, Worcester, and Holyoke one. From *malarial fevers*, New York eight, St. Louis and New Orleans, seven, Brooklyn four, Charleston three, Chicago, Boston, Baltimore, and New Haven one. From *whooping-cough*, New York eight, Chicago six, Brooklyn three, Philadelphia and Providence two, St. Louis and Fall River one. From *puerperal fever*, Boston three, Chicago two, New York, Philadelphia, Brooklyn, St. Louis, Cincinnati, New Orleans, District of Columbia, Milwaukee, and Providence one. From *erysipelas*,

Philadelphia and Providence two, New York, Brooklyn, Chicago, and Charleston one. From *typhus fever*, New York three.

Twenty two cases of small-pox were reported in Brooklyn, 29 in Chicago; diphtheria 28, scarlet fever five, in Boston; scarlet fever 15, diphtheria eight, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,083,543 (population of the State 1,783,086), the total death-rate for the week was 15.64, against 18.24 and 17.75 for the previous two weeks.

For the week ending June 4th in 149 German cities and towns, with an estimated population of 7,878,615, the death-rate was 25.6. Deaths reported 3883; 1833 under five; pulmonary consumption 565, acute diseases of the respiratory organs 362, diarrheal diseases 180, diphtheria and croup 113, scarlet fever 90, whooping-cough 50, typhoid fever 53, measles and röteln 43, typhus fever (Königsberg six, Stettin, Tilsit, three, Erfurt two, Frankfurt 13, small-pox (Königsberg, Munich two, Berlin three, Guben, Hamburg, Aachen five) 13, puerperal fever 10. The death-rates ranged from 15.7 in Hanover to 38.8 in Chemnitz; Königsberg 20.3; Breslau 28.8; Munich 37.8; Dresden 24.3; Berlin 26.8; Leipzig 26.8; Hamburg 25.5; Bremen 27.8; Cologne 28.7; Frankfurt 16.7; Strasburg 33.3.

For the week ending June 11th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 18.8. Deaths reported 2737: acute diseases of the respiratory organs (London) 216, measles 106, whooping-cough 91, small-pox (London 59) 63, scarlet fever 55, diarrhoea 45 fever 27 diph-

theria 14. The death-rates ranged from 14 in Brighton to 23 in Sheffield; Bristol 17.4; London 18.3; Leeds 18.5; Birmingham 18.8; Manchester; 21.7; Liverpool 22.7; Sheffield 23. In Edinburgh 20.5; Glasgow 18.

In the 21 chief towns of Switzerland, for the week ending June 11th, population 479,934, there were 29 deaths from acute dis-

eases of the respiratory organs, diarrhoeal diseases 26, measles 14, diphtheria five, typhoid fever five, small-pox four, whooping-cough two, puerperal fever one. The death-rates were: Geneva 18.2; Zurich 25; Basle 26.8; Berne 26.8; St. Imier 14.5.

The meteorological record for the week in Boston was as follows:—

PRIVATE PRECEPTORSHIP IN THE STUDY OF MEDICINE.

AN ADDRESS DELIVERED BEFORE THE MAINE MEDICAL ASSOCIATION, JUNE 21, 1881.

BY WILLIAM WARREN GREEN, M. D., PRESIDENT.

GENTLEMEN OF THE ASSOCIATION,—The first section of our constitution defines the objects of this Association to be: "Mutual professional improvement; cultivation of friendly intercourse among its members; faithful support of regular and honorable practice; and the promotion of medical science." It was the evident intent and desire of the founders of this organization, as I believe it to be of its present members, that it should represent and encourage all that is best in the character and interests of our profession.

By a rule of the Association it becomes the duty of your president, in his annual address, to suggest such subjects for discussion and action as seem to him for the moment of paramount importance. This applies more directly to matters of local interest in our own State, but it is obviously susceptible of a broader interpretation of which I shall claim the privilege to-day. From the number and character of its members this Association is an influential body. It represents the best thought and the most advanced views of the profession in this commonwealth, and its expressed convictions should constitute a factor of no mean value in molding and directing medical opinion and practice without regard to geographical limits. For this reason I improve an opportunity of inviting your earnest attention to a subject that lies uppermost in my mind, and which, in my opinion, overshadows all others in magnitude and importance. The question of questions, as it seems to me, before the profession at the present time is *how to attain to a higher standard and a better system of medical education?* I do not use the phrase, nor do I intend to treat the topic, in any hackneyed sense or manner. I mean to speak of what is vital and practical. Can we not promptly and in a most important degree improve upon our present plan?

It is unnecessary in this presence to enter upon a comparison of the present status of medical science—I use the term in its comprehensive sense—with that of a hundred, or fifty, or even twenty years ago. But not a little reflection and a careful survey of the field are essential to anything like a full realization of the wondrous strides the different departments have taken within a few years past, and of the present rate of progress.

The same is true of the entire circle of natural sciences with which medicine holds such close derivative and reactive relations that one cannot acquire a sound medical education without an elementary knowledge, at least, of these allied branches. Men are becoming more and more interested in the study of themselves and their environments. They are shaping their methods of inquiry more nearly in accordance with the scientific plan. The what, the how, the why, these are the questions of the hour that have taken hold of the human mind with an incremental force of which only thoughtful men are aware.

Every department of medical science has been, for the last few decades, and still is, rapidly enlarging its domain. Each is constantly demanding higher capa-

ilities and harder toil while promising richer rewards to earnest, appreciative labor. New continents and islands, seas and channels, shoals and quicksands, are being daily discovered, and he who aspires to the position of navigator must read aright not the old chart only, but the new as well. But whoever carefully considers this great progress, and fully appreciates the demand that medical science rightfully makes in our day, cannot fail to be surprised, amazed even, to find that so little comparative change has taken place in the scope and methods of medical education, and that a system born of a primitive and imperfect civilization still holds sway; true, much has been accomplished within a few years in the way of improvement. The medical colleges throughout the country have generally lengthened their lecture terms and enlarged the curriculum of study, and in most cases are doing more thorough work. In many the standard for graduation has been raised, and a few require a certain amount of preliminary education as a prerequisite for matriculation. Most of the colleges have established supplementary courses of instruction under various names which fill out the year, so that the student can if he chooses pursue his studies for the entire three years in the same institution. The Portland School for Medical Instruction holds such relation to the medical department of Bowdoin College.

In all these improvements the Medical School of Maine stands squarely in the front line, and to the honor of the Maine Medical Association be it said that by suggestion and advice, by hearty coöperation and staunch moral support, it has always strengthened the hands and encouraged the hearts of the faculty in every progressive step.

It is cause for congratulation and honest pride that, as compared with ten or fifteen years ago, better classes of men are annually graduated from the schools, and that the general tone and character of the profession has much improved, and is still improving. Nor in point of attainment, honorable character, and professional *esprit du corps*, will the medical men of the Dirigo State suffer in comparison with those of any other.

I have the gratifying assurance from several most eminent members of the legal profession in our State that the act "To regulate admission to the bar in this State," passed by our last legislature, owes its origin to the interest and spirit of emulation awakened among lawyers by the greater strictness of requirements and thoroughness of work in our medical schools as encouraged and sustained by this Association. But it will be noticed that all change and progress has been on the part of the medical schools. It is toward these that all criticism is directed, and in them all hope for the future seems centred. The conviction is gaining ground that the term of study required should be extended, and the profession are generally in sympathy with whatever will render the lecture courses proper more effective.

The regular course of lectures is invaluable, and will probably always stand as a part of any plan of instruction. The concise, systematic grouping of truths, the pointing out of landmarks and boundary lines, the sifting the true from the false, and the authoritative presentation of general principles and of the best approved practice in a concrete form, is the province of a living teacher. No mere study of books and recitation can ever be complete without this. Certain kinds of knowledge take deeper root when received warm and

fresh from the lips of the teacher. Old truths take new shape and brighter color as they flash from the living brain. It is fit that students should be brought into direct contact with those fitted by fullness of knowledge, experience, and practical skill for the high vocation of teachers. Ambition is stimulated and enthusiasm aroused in the lecture-room and amphitheatre as nowhere else.

It is true that the term of three years is altogether too short if ever so faithfully and wisely improved. It is true, also, that much remains to be done in improving and perfecting the lecture courses. But a student is only required to take two of these before presenting himself for graduation, and this is probably enough in proportion, and these occupy only from a fourth to a third of the whole time. *What of the other two thirds?* To be sure, as I have already said, opportunities are offered in the various schools for continuous study, and in several instances a regularly graded course may be pursued for the whole time under accomplished teachers and professors. But it is entirely optional with the student whether or not he will avail himself of such privileges. With his certificate of time from his preceptor, and two courses of lectures in a reputable medical college, he stands just as well before the law as if he had spent his whole time in the best school; and as a fact but a very small fraction of the whole number of medical students is in the schools.

Gentlemen, I believe that the great defect in our present system is *private preceptorship*. It is the great hindrance to thoroughness and the grand obstacle to a most pronounced and rapid elevation of the standard of medical education and of the character of the profession.

At present any physician in regular standing may take students, and his certificate of three years' study by such student under his tutorship is evidence which the faculty of any medical college is obliged to accept. No conditions are imposed as to learning, skill, morality, aptness to teach, or facilities for teaching.

Just think of it! no matter whether he has a library, dissecting-rooms, chemical laboratory, microscope or not, or if he has, whether he is competent to direct to their proper use or not, if he has a diploma, and occupies a nominal position in the profession, he is competent, under the law, to take charge and direction of the highest and noblest form of education; to fit men for the heaviest responsibilities that pertain to human life.

However well educated and equipped with the means of study, there are comparatively few men who are born teachers, that is, who possess that natural fitness which enables one to impart his knowledge to another in a clear, methodical, and impressive manner.

The first unfortunate tendency of this system is to bring to the study of medicine a large class of men who are utterly unfit for the work as regards preliminary knowledge. Physicians generally are anxious for students. Various motives are operative. A certain popular *clat* attaches to preceptorship, and personal advantage and convenience are often served. Men are often tempted, especially among their patrons, to flatter aspiring youths, or at least they lack the moral courage to give advice that produces mortification and disappointment. The feeling of responsibility to the profession and community is comparatively slight, and is too frequently counterbalanced by a mistaken sympathy for those who, having failed in other pursuits, look to the practice of medicine as a *dernier resort* for retrieving broken fortunes.

There is room for honest difference of opinion as to the best kind of educational fitness for the study of medicine. But I do not fear successful contradiction when I affirm that, with the present aspect of medical science, no man is prepared for its successful study who does not at least possess, in acquired knowledge and mental discipline, the equivalent of a good college education. This is not an exact expression, but will serve for illustration. As to the details of the preliminary course wise men hold different views. For one, inasmuch as the technicalities of all science are of classic origin, and as these terms are essential to precision and accuracy of statement, I believe such knowledge of Latin and Greek as gives a ready understanding of these terms to be of immense value. Without it one must always work at disadvantage. It is no argument against the need of classical knowledge that the technical expressions are often unfortunate of application. They always have their meaning *per se*, and a prompt appreciation of the very misapplication is of great use. Equally important do I hold at the present day such knowledge of French and German as will open to the student the rich stores of material that fill the journals and untranslated monographs from the pens of the best men in these nationalities, and which are sealed to him who only understands English. But in the absence of such attainments so much the more time should be spent in the study of English literature, mathematics, and the various branches of natural science. Especially should a thorough knowledge of natural philosophy, chemistry, and physics generally be insisted on.

In short, the student should come to his chosen work with a mind stored with general knowledge, and trained to habits of sound reasoning and to the quick apprehension of new truths.

Moreover, he should be a true gentleman.

How far the majority of medical matriculants fall below this standard needs no demonstration at my hands. We have only to look and see.

It is a painful evidence of the low estimate which the public place upon the necessary fitness for medical study that we are constantly receiving applications from men so illiterate that they cannot write a decent letter, as to spelling or punctuation, use of capitals, or arrangement of sentences, and who are entirely deficient in the elements of a good common school education. It is a sad commentary upon the character of private preceptorship that a large number of students repeat the advice of their preceptors that they had better not pay much attention to chemistry or physiology or the microscope. "They will not use it much in practice," and they act upon such advice. These students avoid dissection, or try to, altogether. Instead of seeking every opportunity for the study of practical anatomy they do only so much as they must to receive the demonstrator's ticket.

I hold that as the profession is constituted it is utterly impossible to secure any uniformity of preparatory fitness so long as any doctor may play the part of preceptor. So long as this may be we shall have our classes heavily shaded with men not only incompetent to study properly, but who incline to do only so much work as will enable them legally to obtain a diploma. In the second place the system of private preceptorship can at best only afford an imperfect and superficial medical education. As has been already remarked, few are apt to teach, and these few cannot furnish the

facilities for instruction that are found in a properly organized school. Those best able and prepared to teach are generally too busy as practitioners to find it possible to bestow any considerable time upon students.

Very rarely a physician is found with a combination of all the requisites for a teacher who can command sufficient leisure for the training of students, but such instances are remarkable and so infrequent as to be of little value in the general scheme.

It is impossible for a busy practitioner to do justice to his patients and himself and give students proper training, be he ever so rich in ability and facilities. Will not every one of us who has tried it say amen to this statement? It may be well for a student to have some wise medical friend who is in full sympathy with what is best as an adviser, and in the later years of undergraduate life valuable additional clinical opportunities would sometimes be gained by such a relation. Undoubtedly, a good plan would be for young graduates to associate themselves for a time with practitioners to see the practical side of professional life. Reciprocal benefits would accrue from such contact.

The general way that a young man studies medicine is something like this: He "enters his name" with some practitioner, who is thus constituted his preceptor. Certain books are given him from time to time which he "reads" after his own fashion. If he has means he may stay about the office, and in some cases occasional recitations are heard, and now and then he rides with the doctor to see patients. Sometimes the student "works his way," as it is called, with the doctor, acting in various capacities as hostler, office boy, gardener, etc. But the majority spend very little time with their preceptors. They take certain books, and in place of studying them to any important degree, they work on farms or in mills, take agencies, teach school, or follow some other lucrative employment; oftentimes for the purpose of earning money to defray the expenses of lecture courses; others, instead of work, pursue their pleasures as they list. An occasional call upon the physician and a few remarks or general questions constitute the tutorship.

I speak of what I know from extensive personal observation, and every man who has much familiarity with the lives of medical students throughout the country will bear witness to the truth of my statement.

I do not forget the honorable exceptions, where good men, both preceptors and pupils, do faithful work, and accomplish the best possible under the circumstances, unfavorable as they may be; but in the large majority of cases, I know whereof I speak when I say that there is nothing approaching a systematic, thorough course of instruction. On the contrary, the student goes his own way, doing what little work he may in medicine in a helter-skelter, slipshod manner, and making it entirely secondary and subordinate to other pursuits of pleasure or profit as the case may be.

And yet these students bring to the medical colleges certificates of time signed by their preceptors, reading after this fashion: "I hereby certify that Mr. — has been a faithful student of medicine and surgery in my office for three full years, and he is a gentleman of unblemished moral character." These certificates are the evidence of *time*, and the faculty cannot "go behind the returns." These men enter for graduation on the same basis, so far as the record goes, with those who have been the most faithful students under the best advantages.

Nor is it a cause for wonder to those who are familiar with teaching that such men graduate. It is not simply because so little is required, although it is very little compared with what ought to be.

With the comprehensive and yet concise character of most lectures many beginners, especially those possessed of what is termed an arbitrary memory, can by a species of cramming, and the note system, fit themselves to pass a fair examination at the end of the term *as examinations go*. What are they? An occasional quiz during the term, in each of which the individual student is asked one or two questions. At the close a written examination of six to ten questions, which are to be answered within two or three hours, and an oral examination occupying from five to fifteen minutes.

It is impossible for the professor in any department to form any thorough acquaintance with a student during a single term in this manner. For as I have said, any bright man can, if he works to that end, fit himself to pass such examinations quite creditably. To be sure such knowledge takes no root, and leaves the man with only a valueless or rather a dangerous smattering of ideas; but it serves his only purpose, the acquisition of a diploma. These are the students who always think the examinations too severe, and find fault if questioned upon any topics not specially dwelt on in the last course of lectures. They are only willing to dissect one part, and do that in the speediest and worst way. They dislike chemistry and cannot see any practical value in its formula or principles, or in the use of the microscope. As one young man said three years ago, "I don't care a damn for all this high-flown theory and these stuck-up Greek and Latin words. What I want is to find out what cures sick folks." So long as this state of things exists, all progress in medical education must be in the future, as it has been in the past, painfully slow and unsatisfactory. I believe the time has come for a complete change. The time has come when it is the duty of every physician to refuse to "take students" in the common acceptance of the term, and to advise them frankly and honestly that the only way to a proper medical education is through well organized medical schools. I believe that all members of the profession, individually and through their various organizations and the medical press, should take pronounced and unflinching position on this question. I am aware of the objection that will probably be first raised to such a plan. It will be said that by it a large number of poor men would be prevented from studying medicine for lack of means to attend the school continuously; which, by the way, is merely saying that they cannot afford to study medicine thoroughly. That such a plan would much diminish the size of medical classes I am well aware, but that it would do so to an undesirable degree I do not believe. Nor do I for one moment admit that by it the *right* sort of men would be prevented from entering the profession. Altogether too many men are studying medicine, and graduating every year. The world has no need of them as doctors, for the profession is already fearfully overcrowded. This may be an unwelcome truth to young aspirants for professional honors, but truth it is; and the evil consequences of this repulsion are manifold.

Witness the large number of doctors in every city, struggling for a mere existence, and see how few out of the whole number really do the work. See how in almost every country village a full practice for one or

two good men is piece-mealed by sharp and often acrimonious competition to the detriment of all.

It would seem that in a calling so high, so noble, so sacred, men fit for such ministry should be sought for; but the great question of the young graduate is not "Who wants me?" but, "Who will employ me?" not "Who needs me?" but "Where can I get a living?" In the case of four physicians dying, each in a country village, during the last year, I am credibly informed that in one instance two, in another three, in the third five, and in the fourth case seven new men came to look the field over within ten days after the doctors' death, sometimes before the burial. In one case two attended the funeral, and in another the widow had three letters from aspirants for the vacant place while the dead body of her husband still lay in the house.

It is a hackneyed saying, with which too many ears are tickled, that "there is always room for good men." Applied to the present condition of our profession it is false. Were only good men and the best men admitted it would undoubtedly be true. But all over the land, in city and country, are well educated, cultured gentlemen, honest and loyal, striving in vain to secure a competence, — yes, a bare living even — and too often is disappointment mingled with shame and mortification at the success of ignorant and unprincipled rivals. I have said that the evil results of this excess in numbers are manifold. It leads to over practice and to bad practice. The man who is hard pushed, who has few patients and needs more, is tempted to make much of little; to magnify the importance of his cases, both in his own mind and to his patrons; to make un-called for visits, and to give too much medicine; and unnecessary medication soon ceases to be rational. Patients are injured in mind and body. The community is injured by teaching the people to attach undue importance to trivial diseases, and to over-estimate the value of treatment therein. Legitimate, honest practice suffers in reputation; money is obtained under false pretences.

Again, it leads to dishonor and crime. There are many men not very firmly grounded in morals or ethics who nevertheless behave commendably until strongly tempted. There are men who are to-day outcasts from the profession on account of dishonorable or criminal practices who struggled long with poverty before they fell, and others who, eking out an income by questionable methods under cover of professional title and association, would much prefer remunerative practice within strictly honorable limits.

It is one great cause that fills the ranks of the more fashionable forms of quackery. Men who have once had a thorough education in scientific medicine never honestly enter upon any exclusive or fanciful system of practice; but, finding no room for sound scientific work, many turn traitor to the truth, and seek bread and butter through an appeal to popular prejudice and ignorance. Most make a square issue with honesty, and practice whatever they please under the colors most fashionable. Others enter upon a system of willing self-deception, until, like the tale-bearer of old, they tell the lie so often that they finally come to believe it themselves.

It leads to a false and pernicious specialism.

Without any special fitness for anything, men, failing to secure general practice, announce themselves as specialists. This suits the public. Specialists and specialists find ready audience among the masses. Ignorant

and superficial general practitioners, too, are ready to countenance these men, being glad for a plausible excuse to shirk responsibilities which they are unfitted to assume.

The result is popular deception as to the merits of special diseases. The specialist deceives himself. A cumbrous and oft-times ridiculous nomenclature develops. General principles and special forms of practice are indulged in that are worse than absurd. The so-called specialist enjoys a false reputation to the detriment of a better class of men. Here, too, is money obtained under false pretences.

The remedy for this professional plethora lies in reducing the supply. This can only be done by placing the standard of preliminary requirements so high, and insisting on a course of medical study so thorough and extensive that the class of incompetents who now enter by cross-cuts and surreptitious methods shall be cut off from all hope of admission.

The matter is not easy of mathematical demonstration, but there is not the least doubt in my own mind, or in the minds of the many experienced teachers with whom I have conversed on this subject, that with our present civilization, the amount of wealth and its degree of distribution, and with a business activity which renders facilities for earning money so numerous and important, any man who has the character for energy and perseverance and the unwavering devotion of special love for his work that are essential to true success in medicine, can enter the profession under the *régime* herein advised. This, too, is the decided opinion of eminent jurists with regard to students of law, and I am glad to find a rapidly advancing sentiment in the legal profession (which is much more susceptible of private preceptorship than medicine) in favor of compelling all students to spend three full years in the law schools. Poverty is no hindrance to the right sort of men. "What," says one, "would you establish an aristocracy of learning?" Yes, indeed, say I. Not for one moment would I advise a system which forbids a man's entrance into the profession because he is poor; I would only compel him to become thoroughly educated for his work. I would say to him: The duties you propose to discharge are so arduous, the responsibilities you seek to assume are so weighty and solemn, the trusts you invite so sacred, and the privileges and rewards that await you, though not in money, are so rich, you have no right to aspire to this unless you are willing to consecrate all you have and are to fitting yourself for a place in this glorious profession. Only brains, love for the work, time and hearty endeavor are necessary to procure means for securing and improving the best advantages. If you are not so endowed and capacitated, stand aside for better men, for there are enough of them. If this is aristocracy, I say *vice Aristocrat!*

I have already said that the remedy, in my view, for these evils lies in putting all medical education in the charge of well-organized schools.

Upon these throw all the responsibility. To these give all the opportunity. Toward the improvement of these in every way let all professional influence and criticism be directed.

The moment in which the profession as a body takes this stand marks the dawn of a new epoch in medical education.

The schools can then fix and maintain a proper standard for matriculation, and can modify and im-

prove it in the light of experience and advancing professional sentiment. With increased patronage our institutions will be encouraged and enabled to increase their facilities, and stimulated to greater excellence in teaching. There will at once arise a desirable increase in the sympathy and interest of the profession, and of the public generally in the schools. Responsibilities will be focused definitely, and the whole scheme susceptible of steady improvement. I love to contemplate in an imagination quickened by a strong faith in early realization, the working of the better plan, and to picture its results even with the old term of study, three years, although a lengthening of the time will inevitably follow in the near future.

Think of medical classes composed entirely of educated men spending all their time under opportunities for the best work, and compelled to do it! Recitations, lectures, clinical lessons, reviews, laboratory work, microscopic, physiological, chemical, anatomical, each and all in proper time and place. Picture to yourselves the change that a few years will bring in the tone and character of the profession under this system. Then we shall have some approximation to a proper balance between demand and supply as regards numbers. Then it is to be hoped that knowledge and skill will find such remunerative employment and honorable recognition that necessity cannot be urged as an excuse for illegitimate or questionable methods of practice. Then shall we begin to see such general excellence in the regular profession and such average uniformity in results among different practitioners in ordinary diseases as shall strengthen the confidence of the people in scientific medicine.

Then shall medical experts display such knowledge and judgment on the witness stand, and testify with such unity of opinion on all ordinary matters as to remove the stigma of disgrace now resting upon this class of witnesses, and medico-legal inquiries shall attain to the dignity and importance they deserve.

Then the false and disgusting specialism so prevalent now shall pass away, and beside the main and earliest natural division of medicine and surgery he who selects a smaller division of labor will do so because of some special fitness or opportunity super-added to a thorough general knowledge and a broad and ripe experience.

Then both profession and people will learn that with properly educated physicians and surgeons specialties are not a necessity, but a matter of taste or convenience.

In short, then will the scope and scheme of medical education begin to be in some degree commensurate with the needs of suffering humanity; and to give something nearer a fitness for the noblest and most sacred work that falls to the lot of man. Fear not, my brethren, that any insidious comparisons will be drawn between then and now. Professor Morse of telegraphic fame still wears his historic laurels unchallenged though the telephone has made the message vocal. The reputation of the fathers in medicine rests on the same sure foundation, and the examples of untiring zeal, sublime devotion, and heroic self-sacrifice that they left for us shine with undimmed lustre, although the truths which they with prophetic eye saw dimly shadowed on their horizon are revealed to us in all their fullness.

The question between the new and the old, so far as merit goes, will always be, not what was the opportunity as compared with now, but how was that opportunity improved; and the same honor and praise await

the man who does his best, no matter in what day he lived, or under what system he worked.

So we who were educated in a time of fewer privileges and more imperfect methods, shall ever claim credit for whatever of earnest, honest endeavor was made and for all attained and accomplished under less propitious circumstances. Nor shall the spirit of jealousy or envy even for one moment find place here. But in the true scientific spirit every member of our profession shall hail with glad acclaim the dawning of a better day; and shall lend willing influence and hearty aid to every movement which tends to enlarge the sphere, and ennoble and strengthen the character of scientific medicine.

Gentlemen, all that is necessary to accomplish this great change is conviction. No money, no legislation, no organization of forces is needed, simply let every member of the profession realize the need and act and advise accordingly, and the work is done, or rather, well begun. I believe that if every member of this association would from this time forth take this position, in three years from now there would not exist such a thing as private preceptorship in this state. Still more, if this Association as a body should put itself plainly on record as indorsing the new way, the effect would be incalculable. The profession, the world over, is ready to give hearty assent. It only needs that some one speak and move, other State societies would immediately take up the theme and the schools could afford to, and would, promptly settle the matter by refusing all private certificates of time. The movement once started, so ripe are the times for it, would, I believe, very soon become universal. It lies in the power of the Maine Medical Association to-day to give such emphatic condemnation to the old plan, and such cordial indorsement of the new as shall awaken the professional mind generally to the great importance of the change. I believe that such awakening would surely and quickly be followed by a profound conviction of the needs of the present time, and that within a few years *private preceptorship* would be a thing of the past.

To organizations, as to men, great occasions for good seldom arise. Opportunities to make history that shall redound to the honor and highest welfare of the race rarely come. Fortunate are they who are equal to the occasion; who improve the opportunity.

COAL-GAS POISONING.

BY HERBERT TERRY, M. D., PROVIDENCE.

ON the subject of coal-gas poisoning there seems to be but little written, though the accident is by no means uncommon, two sets of cases having come under my notice during this winter.

January 1, about four A. M., I was called to a family consisting of father, mother, daughter, niece, and nephew. Their sleeping rooms were on the third floor, and were heated from a furnace in the cellar. Shortly after three the daughter awoke with a sense of suffocation, a distressing headache, and nausea which was soon followed by vomiting. She attempted to arouse the mother, and was in part successful. The noise awakened the father. Not realizing the trouble he questioned the mother, but could get from her only: "They're all just so! They're all just so!"

This she repeated over and over again. She has since told me that she knew what she was saying, but "felt too silly to say anything else."

After the father had been awakened, the daughter fell at once into an unconscious condition, but she was, with some difficulty, made to get up and dress, while the father came for me. Under the influence of fresh air and the excitement she recovered in a short time. She was left in a dazed condition, with deafness and headache. The effect on the father seemed similar to intoxication by alcohol. There was confusion of ideas, thickness of speech, and staggering. A severe headache kept him at home during the day.

The nephew (twelve years old), seemed at the time to be least affected. He was crying with a headache, and there were vomiting and purging, but the nervous symptoms seen in the other cases were wanting. For several days, after the others had recovered, he complained of loss of appetite, nausea, vomiting, and headache.

The niece, when found, had attempted to get up, but had fallen on the floor, where vomiting and extensive purging had taken place. When seen she had a quick, weak pulse; rapid, stertorous breathing; hot, moist skin; widely dilated pupils. She complained of being cold, and there were very severe rigors. She needed little attention, and was able to get up by eight A. M. Headache, giddiness, and dullness of perception, lasted through the day.

The mother seemed to be the most profoundly affected. Purging had occurred before I arrived, but she did not vomit until some time after. She was unconscious and breathing very rapidly, with considerable stertor. The pulse was quick, and almost imperceptible, the skin abnormally warm; the pupils widely dilated. She could be roused by slapping the face or shouting in the ear, but would sink into a comatose state immediately. This condition of things lasted, perhaps, half an hour, when convulsions suddenly appeared. They would begin by a loud complaint, such as, "Oh! my head!" followed by a short tonic spasm, and ending in a series of clonic spasms lasting several minutes. There would then be an interval of quiet, lasting perhaps three minutes, followed by another convulsion. About 6.30 A. M., she became perfectly conscious, and on account of a headache, which seemed to be excruciating, I determined to feel my way with small doses of morphia. Accordingly gr. $\frac{1}{2}$ of the sulphate was given, and in a few minutes she was totally unconscious, and so remained for half an hour. The breathing was very slow, the pulse rapid and weak. Twice the breathing seemed to stop, and artificial respiration was resorted to. For a short time the pulse was imperceptible at the wrist. No more morphia was given, though I cannot believe that this small amount can be blamed for the alarming symptoms following its administration here. At ten A. M. all the symptoms that remained were headache, deafness, sluggishness of thought, and prostration. She did not leave the bed for several days.

Dr. A. D. Weeks kindly saw these cases with me, but when he arrived they were so far recovered that he did not think it necessary to suggest any additional treatment.

February 18, a man and his wife were found under the influence of coal-gas in a house of which they were the only occupants. The man's sister called about eleven A. M. Not gaining admission, and remembering

that the wife was ailing the night before, she went to the window of their bedroom, which is on the ground floor. The man was lying diagonally on the bed, the wife lying across his chest. The sister, instead of fainting, got a chair and crawled in at the window.

I arrived at 11.30 A. M. Both were insensible and frothing at the mouth. Respirations 36 a minute, both stertorous and blowing; pulse in the man 124, in the woman 132; skin of the face and arms reddened (not purplish). Surface of the body warmer than natural, and somewhat moist; pupils not sensitive to light, and slightly larger than normal, but not so widely dilated as in the other cases; eyes partly open; conjunctivæ not sensitive to the touch. Both were motionless after even a very severe slap on the face, unless it was several times repeated, when a slight and slow wrinkling up of the features would occur. Vomiting and extensive purging had taken place in both, apparently some hours before. The stench was horrible, but I think characteristic. It was the odor of coal-gas partly disguised and made infinitely more disagreeable by that of the dejections. The muscles were rigid, and the mouth firmly closed.

12.30 P. M. The wife now began to notice those around her, and when approached seemed to try to shrink away as if in fear. The man was still unconscious, but as the last few drops of brandy left the hypodermic syringe, his arm would be drawn up a little and very slowly. Touching the conjunctiva would cause a slow and incomplete closure of the eyelids.

1 P. M. The wife answered a question shouted in her ear by a slow nod of the head. The man's condition was unchanged. It was noticed that no movement of the eyelids took place when the hand suddenly approached the eye.

1.30 P. M. The woman could speak, but only with great difficulty, and in monosyllables. She would say over and over again, "Cold! Cold!" though the surface of the body was very warm. She was fully satisfied with a hot bottle to hug. She could hear only very loud talking. The man seemed to breathe easier, but there was still considerable stertor. The breathing would seem to stop every few moments, but would start up again when the air was pressed out of the thorax. The pulse had grown worse rather than better. It was now 128, and very weak. Tincture of digitalis was added to the brandy in the proportion of twenty minims to the drachm, and half a drachm of the mixture repeatedly injected beneath the skin.

2.30 P. M. The wife was washed and removed to another room. She seemed quite rational, and began to understand that we were not thieves. Her hearing gradually came back, and she continued to improve without further treatment. The man's pulse showed a marked improvement from the digitalis, but he was still unconscious.

4.30 P. M. The woman could sit up, but her pulse remained at 130. The man's pulse had come down to 108, and was proportionately stronger. The breathing, which for some time had been irregular, was now noticed to be regularly so. He would breathe ten times during twenty to twenty-two seconds, at first very shallow, the depth and strength increasing up to a certain point, when it would gradually diminish until it stopped. There would then be an interval of eight or nine seconds, when he would again breathe ten times. Rarely it was nine, and still more rarely eleven times. He could be made to breathe during the inter-

val by any irritation, for example, by slapping the face or forcible pressure on the thorax. A loud shout, with a slap on the face, would now elicit a grunt of vexation, the first sign of consciousness five hours after being discovered.

5.30 P. M. The man was more easily roused, and could be made to swallow by pouring the liquid into mouth and holding the nose. When the nose was not held spasm of the glottis followed.

6 P. M. The wife was sitting up, feeling only a little dizzy and confused. Pulse 120; temperature 100.6° F. The man was still in a comatose condition. Pulse 104, and quite good.

8.30 P. M. The woman's pulse was still 120, and by no means full. The man had just been washed and moved, and as a result his pulse was 120, and weak. Brandy, two drachms, and tincture of digitalis, twenty minims, were given. Percussion over the puses showed a full bladder, and on being roused and made to understand what was wanted he emptied it by his own efforts.

9 P. M. The man's pulse was 100, and of fair strength. Orders were left for brandy to be given through the night p. r. n.

February 19th, 9 A. M. Night report: "The man became conscious of surroundings about 3 A. M. (that is, sixteen hours after being discovered), since which time he has been very nervous. About one ounce of brandy has been taken during the night, and early in the morning a cup of strong coffee." The man was found still in bed. Pulse 96; temperature 99.8° F.; respirations 26. He could hear and understand with but little difficulty. In answer to a question, "How do you feel?" he whined, "I don't know." When undisturbed he lay with the eyes closed, apparently asleep. A very troublesome cough was present, and the chest was filled with mucous râles. The woman's pulse was 100; temperature 98.4° F.

5 P. M. The man was sitting up. Pulse 100; temperature 101.8° F.; respirations 28, and of good character. The cough was still troublesome. There was no dullness on percussion over the lungs. Large moist râles abounded. Both patients complained of ringing in the ears.

The treatment, in all the cases, was fresh air and alcoholic stimulants. In one case the pulse would not respond to the brandy, and tincture of digitalis was added. This seemed indicated by the hot, moist skin (dilated arterioles?), as well as the quick, weak pulse. Its action was marked and most happy. Artificial respiration was resorted to in one instance, but I think unnecessarily.

Comparing the two sets of cases: there were in both unconsciousness and loss of sensation and voluntary motion, violent vomiting and purging, a quick and weak pulse, rapid and stertorous breathing, an abnormally warm skin (not at all like the hot, dry skin of fever), pupils at least slightly dilated. In one case the breathing was blowing as well as stertorous. A characteristic of the first set of cases was violent headache. It was entirely absent in the last. Convulsions may have occurred in the man and wife. I should think it very likely from their position when found, and the pretty good evidences of their having moved about after purging took place. I cannot but think that hysteria was an important factor in the production of the rigors in the niece, as well as the convulsions and the coma that followed the administration of

one twelfth of a grain of morphia in the mother. They are both nervous people.

I regret that the temperature in the last two was not taken while they were unconscious. It was slightly above the normal after consciousness returned.

The cause of the first set of cases was the worn-out condition of the partition separating the fire from the air-box containing the air passing to the rooms above. Whether the coal-gas went up the chimney or through the registers depended on which way the draft was the stronger. On the night when the poisoning occurred the door in the furnace flue was accidentally left open, reducing the draft up the chimney to little or nothing. The result has been detailed.

The cause of the other cases of poisoning was an insufficient draft to the chimney when the wind was in a certain direction. A "parlor stove" was left with both the back-dampers closed.

In both cases the smell of coal-gas was noticed when the families retired.

For some of the post-mortem appearances I am indebted to two cats. These were placed in a wooden box, in the cover of which was a pane of glass, that they might be observed. By means of a Davidson's syringe coal-gas was pumped into the box from the reservoir of a self-feeding coal-stove.

The first cat was sick before the experiment began. During the afternoon she vomited two quite long worms. At 9.50 P. M., when she was placed in the box, the pulse was 144, the respirations 60. About 10 P. M. the bladder was evacuated; the pupils were noticed as very widely dilated; the pulse and respirations became very frequent. Ten minutes after, she apparently died, with hardly a struggle.

Fifteen minutes after death. No cyanosis; pupils widely dilated; mouth slightly open and tongue protruding. The blood was bright red and fluid. The left ventricle was firmly contracted, the right soft and flaccid, but not dilated. After opening the thorax the right auricle beat rapidly and sharply for a full minute, after which it beat slower and slower until it stopped. No part of the head presented anything abnormal, not even enlarged blood-vessels. The stomach and small intestines contained only a little mucus; the large intestine was packed, from valve to anus, with hardened feces. This abnormal degree of constipation may explain the absence of purging. Rigor mortis came on in less than half an hour after death.

In the second cat, at the beginning of the experiment, the pulse was 130, respirations 24, and purring. The gas was introduced at 9.15 P. M. The cat soon fell quietly asleep, and at 9.35 P. M. she could not be roused by pounding or shaking the box, though when loudly called would start up for an instant.

9.50 P. M. Pulse 180; respirations 144. There was a copious movement of the bowels.

9.55 P. M. Pulse 220; respirations 156.

10.10 P. M. The cat was perfectly insensible; mouth open; tongue lolling; respirations very shallow and irregular; pupils widely dilated; eyes partly open; conjunctivæ still sensitive. The cover of the box was taken off, so that the chest might be examined. Sibilant and large mucous râles were found. The pulse became very irregular, jumping about between 160 and where it could not be counted. (This must have been beyond 240, for that could be counted by moving the finger every fourth beat, and having another count the finger-beats.)

At this stage of the experiment a high wind sprung up, and all my coal-gas went up chimney. The cat soon became conscious, and, barring a little weakness, was apparently as well as ever in less than an hour.

The experiment was concluded the next day. 3.03 p. m. The gas was again introduced. 3.05 p. m. There were a few squalls, probably from fear rather than distress. 3.08 p. m. A movement of the bowels occurred. This might have been due to fear. 3.10 p. m. The cat became too weak to stand, and lay down on the side voluntarily. 3.12 p. m. There was a sudden contraction of the muscles. I could not determine whether it was an attempt to get up or really a convulsion. It was momentary, and not repeated. 3.14 p. m. The conjunctiva no longer sensitive; pupils enormous; iris a mere ring; pulse 156. Each inspiration was a jerk resulting from a sudden spasmodic contraction of the diaphragm, and recurring regularly every three seconds. The cover was taken off the box and fresh air admitted. 3.18 p. m. Respirations 40, and quiet, with an occasional sigh. I find no note of the pulse. 3.20 p. m. The conjunctiva became sensitive, as well as the small hairs on the end of the ear. The gas was again admitted. 3.27 p. m. Breathing 104. 3.30 p. m. The cat suddenly got upon her feet, struggled blindly for a time, and at 3.32 died. Autopsy at ten p. m. Mucous membrane of lips and tongue a light red. Ramifications of the small vessels on the under side of the tongue plainly visible. Care was necessary in cutting through even the skin, for the smallest blood-vessels would bleed. Both arteries and veins contained fluid blood, which was lighter in color than arterial blood usually is. The right heart was flaccid and very much distended. The left heart contained blood and was quite soft. Lungs collapsed and very much congested. Froth, but no blood, came from the smaller tubes on section. The stomach was very much distended with gas, which had the characteristic odor of coal-gas. In cutting through the skull the vessels of the diploë bled profusely. The vessels of the arachnoid were more prominent than usual, and looked as though formed in red sealing-wax. There was no capillary congestion. The brain was, if anything, lighter in color than usual.

Some of the blood kept in an open dish was found fluid at the end of two days. The blood globules at the end of the first day (they were not examined before) were so broken up as not to be recognizable.

These cases and experiments are by no means conclusive, and I offer the following as only possibly true:—

The fatal effects of coal gas are probably from the carbonic oxide contained. Carbonic anhydride is irrespirable only, carbonic oxide, poisonous. The color of the blood after death showed the presence of carbonic oxide. To destroy life carbonic anhydride and sulphurous anhydride would have to be in larger quantity compared with the amount of oxygen present than generally found in poisoning by coal gas.

The primary action of coal gas is (if we except the fact that carbonic oxide changes the properties of the blood globule) on the nervous system. This is suggested by the occurrence of vomiting and purging in addition to the rapid pulse and breathing, coma, dilated pupils, etc.

The presence of the same relative amount of coal gas in the air inhaled, affects different persons differently. This is shown by the cases.

The length of the period of unconsciousness depends more on the time occupied in breathing the coal gas than on the degree of unconsciousness produced. This is suggested by a comparison of the cases with the cat in the second experiment.

Or it might have been due to the difference in cerebral development.

NOTE.—March 13th, I was called to the man spoken of in the second set of cases. Two years ago he had had a slight attack of hemiplegia (right) from which he recovered in a few weeks. He has not felt quite as well since that time. I had not seen him since his recovery from the effects of the coal gas, but his wife told me that he had been very rapidly losing his memory. I found him with most of the early symptoms of general paralysis, and March 14th he was admitted to the Butler Asylum.

The following is an incomplete list of articles bearing on the subject:—

RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

EXTIRPATION OF THE CARCINOMATOUS UTERUS THROUGH THE VAGINA.

THE operative procedure as adopted by Schröder and described by him in a paper presented to the German Gynaecological Society at the fifty-third annual meeting of German Naturalists and Physicians, held in Dantzic,¹ consists in inserting a Muzeux forceps into each lip of the os and drawing the uterus downward. The vagina is then cut through round about the portio vaginalis, which is often much thicker than is generally supposed. The separation of the bladder from the cervix may be accomplished without difficulty, the connective tissue between the two organs being loose and easily separable. The bladder escapes upward, which greatly protects the ureters from injury. The posterior surface of the uterus must next be freed.

¹ *American Journal of Obstetrics*, January, 1881.

Douglas's pouch is opened, the two folds of which during the forcible traction downward, are often close together. The scissors may be used to widen the posterior opening. The uterus is then inverted from behind. This is easy at times, but very difficult when the organ is large and stiff. After inversion, the uterus lying in the vagina, the peritoneum of the vesico-uterine excavation is cut into, and the uterus is then attached only to the broad ligaments. These are not easily disposed of; the hæmorrhage is not large, the downward traction preventing it at first, but secondary hæmorrhage is to be feared. In ligating, Schroeder preferably leaves the tubes and ovaries in the pelvis, because the pedicle thus obtained is longer. Dividing above the ovaries prevents the place of ligation from being drawn into the vagina or fastened there. The spermatic arteries, together with the infundibulo-pelvic ligament, draw upwards. For this reason, in one case cited by Schroeder, a very difficult and tedious circumligation was required. Ligation may be performed *en masse*, or in portions, or both. Division then being made close to the uterus on one side, the uterus may be drawn down with great facility, and the ligation of the other side is much easier. Both stumps are sewed into the vagina, and a drainage tube inserted into the central opening. Schroeder sews with silk and ordinary curved needles, first laterally outward, and the stump almost between the two margins of the vaginal wound, so that possibly bleeding vessels or discharging wounds project into the vagina. Be the uterus ever so friable, the operation is still possible. Should it be adherent, he would separate benign adhesions from the malignant fixations. Benign adhesions are easily separated, but those caused by the formation of tumors tear.

That the prognosis is good is asserted not from statistics merely, but from the impression made on those who have recovered, an easy convalescence being the rule. An important fact in favor of the operation over laparotomy is the absence of collapse or shock, even after much loss of blood. Schroeder's cases reacted like puerperæ after considerable hæmorrhages, the recoveries being rapid and perfect, and impressing him greatly with the important difference between the superior and inferior methods of operation.

Many cases do not occur in which the entire uterus must be extirpated. It must, however, be done in affections of the cervix. The vagina may be likewise affected, but the section must extend to one, possibly to two, centimetres from the new formation. Thus the operation finds its limits.

Counter-indications: (1.) When carcinomatous nodules can be demonstrated in the pelvic connective tissue. (2.) When not only extensive infiltrations exist, but also quite small nodules, as often demonstrated by careful palpation in Douglas's folds. (3.) In carcinoma corporis, laparotomy, in which operation the body of the uterus alone is removed, being often much easier and less dangerous. In carcinoma corporis, laparotomy, with amputation at the internal os, might become the typical operation. (4.) When the size of the uterus is too great, the operation being most easy in a roomy pelvis and ample vagina.

CANCER OF THE BODY OF THE UTERUS.

Veit¹ has himself observed twenty-one cases in three years. He concludes that carcinoma of the

body is always beyond any doubt a glandular carcinoma. Different forms occur, depending on the early disintegration of the new formation; so that as the degeneration increases layer by layer the cavity becomes larger, while the neoplasm itself is not thick. But a circumscribed spot may become affected, and a node form from that starting-point. In other cases the uterus is tense, and large nodes spring from it. No case has been observed in which the mucosa was not implicated. The musculature has but a slight tendency to carcinomatous degeneration; the peritoneum rarely participates. Veit favors the view as to its origin from adenoma. Microscopical examination determines the diagnosis. The most important characteristic symptom is the intermittent, labor-like pain.

TREATMENT OF EXTRA-UTERINE PREGNANCY.

Dr. Lusk² cites several cases of extra-uterine pregnancy in which faradization and galvanism have been effectually used.³

In the larger number the faradic current was employed, and of these his own case was one. Faradization in extra-uterine pregnancy was first successfully used by Dr. J. G. Allen, who reported in 1872 two cases of recovery through its instrumentality. So far, since then, his method, faithfully carried out, has proved uniformly successful, has presented no drawbacks, and all the women are known, from private inquiry, to be enjoying good health at the present time; while of one hundred and fifty cases of tubal pregnancy collected by Hennig only seventeen survived.

The transmission of the current through the ovum has thus been proved a safe and efficient means for destroying the life of the fetus, during the first three months of its existence. The application consists in passing one pole into the rectum to the site of the ovum, and pressing the other upon a point in the abdominal walls situated from two to three inches above Poupart's ligament. The full force of the current of an ordinary one-cell battery should be employed for a period varying from five to ten minutes. The treatment should be continued for one or two weeks, until the shrinkage of the tumor leaves no doubt as to the efficacy of the treatment.

ENUCLEATION OF SUB-PERITONEAL FIBROIDS THROUGH THE VAGINA.

Professor Czerny, of Heidelberg, reports⁴ several cases where he enucleated sub-peritoneal fibroids through the vaginal cellular tissue without opening the peritoneal cavity, and others where the peritoneum, being slightly injured, was immediately closed. Some of the fibroids were in the broad ligament and some in Douglas's fossa, while one was between the bladder and uterus. His plan is, by dissecting with blunt instruments, to tear his way to the tumor, and then drag it out, cutting as little as possible. The results were good. The operation has been done a few times only, but he thinks it deserves attention.

Although the cases have not yet been reported, Dr. Marcy, of Cambridge, has twice within eighteen months done this operation, once with great facility and success. In the other instance, the peritoneal cavity was opened through Douglas's fossa, and an ovary re-

² American Journal of Obstetrics, April, 1881.

³ One of these cases, that of Dr. J. C. Reeve, was made the subject of a paper at the last meeting of the American Gynecological Society.

¹ American Journal of Obstetrics, January, 1881.

moved at the same time with the fibroid, the patient making a less perfect recovery.

As early as December, 1876, Dr. Van Derveer, of Albany,¹ most successfully removed through an incision in the posterior vaginal wall, without wounding the folds of the peritoneum, a fibroid, which he was inclined to consider interstitial.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

SERVICE OF DR. BEACH.

ANTISEPTIC SURGERY.

REPORTED BY MR. WILLIAM D. HODGES, HOUSE PUPIL.

COMPOUND FRACTURES.²

UNLESS otherwise specified the Lister carbolic-acid dressing was applied in the following cases:—

CASE I. A boy, sixteen years old, entered with a compound fracture of the radius, at its middle, caused by a circular saw, which also made a wound of the soft parts through one third of the diameter of the arm. The opening was enlarged, and the ends of the bone were wired together. Union on the twenty-eighth day. Splints and dressing removed. Three weeks afterward had an attack of erysipelas about the wound, during which the latter opened spontaneously. Dressing reapplied. Wire removed on the fifty-fifth day. Discharged well, with a good union. Temperature on the day after admittance 101° F.; from that time until the seventh day it gradually fell to normal, and remained normal, or very nearly so, during the rest of the time.

CASE II. A man, aged fifty-six. Three hours before entrance sustained the following injuries: a dislocation of the head of the humerus backwards; fracture of the shaft of the humerus just above the condyles, and a compound fracture of both bones of the fore-arm at the junction of the middle and lower thirds. The dislocation had been reduced before entering the hospital. A "phenyle" dressing was applied to the compound fracture, and splints as usual. The compound was reduced to a simple fracture on the fourteenth day. Discharged, well, on the fifty-second day. Temperature highest on the second day, — 100.5° F., — normal during the rest of the time.

CASE III. A man, aged thirty-two. Compound comminuted fracture of the humerus extending into the shoulder-joint, caused by being thrown violently on to a rock during a blasting accident. Excision of the head of the humerus. Twenty dressings applied; omitted on the fortieth day. Temperature highest on the tenth day, 102° F.; during the rest of the time within normal limits. Carbolic-acid poisoning occurred after the seventh dressing. "Phenyle" dressings were substituted, after which the poisonous symptoms from carbolic-acid absorption disappeared, and did not reappear.

CASE IV. A man, twenty-eight years old, was thrown under a car-wheel four hours before entering the hospital, and received a compound comminuted fracture at the middle of the humerus, complicating the elbow joint, and extensive lacerations of the arm, fore-arm, and hand. Amputation at the shoulder-joint. Fifteen dressings. On the thirty-second day the dress-

ing was removed, only a small granulating spot remaining. Temperature during the first three days ranged between 100° and 102.5° F. On the sixth day it was normal, and remained so until he was discharged well on the sixty-fourth day.

CASE V. A man, twenty-one years old. Compound comminuted fracture into the elbow-joint from a railroad injury. His general condition forbade any operative interference for three weeks after the injury, when the whole joint was excised. Sixteen dressings applied. Discontinued on the thirty-ninth day. Discharged on the fifty-fifth day after the operation. Temperature highest on the third day, 103° F., and, with slight variations, was normal during the rest of the time. Reports eight months after the operation that he can do as much and more with the injured arm than with the other.

CASE VI. A man, thirty-two years old. One hour before entrance, his arm was crushed between the bumpers of two cars, causing a compound, comminuted fracture of the humerus into the elbow-joint. Complete excision of the joint by the sub-periosteal method. Instead of using carbolic acid as an antiseptic, "phenyle" was substituted, both in the gauze and the solution for the atomizer and instruments. Seven dressings. Patient walking about the ward on the tenth day. On the twenty-sixth day all dressing was omitted. Only once after the operation did his temperature reach 100° F. During the remainder of the time it ranged between 98.5° F. and 99° F. He was discharged well on the thirtieth day, able to flex and extend the fore-arm. Pronation, supination, and the movements of the fingers and wrist-joints were nearly perfect.

CASE VII. A man, aged thirty-two. Railroad injury of one hour's duration. Colles's fracture of the right radius; dislocation of the ulna backwards and fracture of the internal condyle of the left humerus; also a compound comminuted fracture of the left radius and carpal bones, opening the wrist-joint. Excision of the wrist-joint, splints, and twenty-six dressings. Temperature highest during the first ten days, when it ranged between 99° and 104.5° F.; during the rest of the time between 98° and 100° F. Discharged on the seventy-first day, when he could raise the hand of the excised wrist to his mouth.

CASE VIII. A boy, aged thirteen. Railroad injury causing a compound comminuted fracture of the radius and ulna, and tearing the hand off at the wrist. Amputation of the fore-arm just below the elbow-joint. Only one artery (the brachial) required a ligature. The Lister dressing was applied as usual; on the third day after, a sudden hæmorrhage took place. A tourniquet was applied, the dressing removed, the wound reopened, and, after carefully detaching the clot, the catgut ligature which had closed the brachial artery was found dissolved at a point opposite the knot, which was intact. There was no evidence of that part of the ligature being weaker than the rest when the vessel was first tied. A fresh ligature was applied, the wound closed, and afterwards four Lister dressings were successively used until the forty-second day, when he was discharged well. Temperature varied between 98° and 100.5° F.

CASE IX. Two years ago, a man, aged twenty-one, received a compound and extensively comminuted fracture of the humerus in the lower third, during a railroad accident. The wound was cleared of loose

¹ Boston Medical and Surgical Journal, October 2, 1879.

² Including all entering during the service.

fragments, including a section of the whole shaft of the humerus nearly one inch long. Dressings were applied until the fiftieth day, when the soft parts had entirely healed; the temperature having varied between normal limits. Splints were applied, and he was discharged, with directions to report occasionally for inspection. Fragments of necrosed bone were removed from time to time. Some months after, all inflammatory action having ceased, and there being no union, he entered the hospital again for an operation. The old wound was opened; the ends of the bone were denuded of periosteum, sawed off, and united by a wire suture; no ligatures required. The dressings were applied as usual, and splints to maintain coaptation and prevent tension upon the wire suture. On the tenth day after the operation he had a hæmorrhage from the wound, and lost between five and six ounces of blood. A tourniquet was applied, the patient etherized, and the dressings removed, when the wound was found to be nearly healed. The source of the hæmorrhage was behind the bone, and on the opposite side of the arm from the wound. There was no alternative but to reopen the wound, remove the wire, turn out the ends of the bone, and secure the bleeding vessel, which had become perforated by a spicula of new bone. The fragments were afterward readjusted and the arm laid in splints. Progress was from this time uninterrupted, and he was discharged well, with a firm union, seventy days after. Temperature during the first five days varied between 99.5° and 102° F. On the fortieth day, when he had a chill, it was 103° F., but after a dressing it lowered, and remained within normal limits afterwards.

CASE X. A man, aged thirty-four, received the following railroad injuries: an incised wound of the forehead, Colles's fracture of the left radius, simple fracture of the tibia and fibula at the middle of the right leg, and a compound fracture of the left femur at the junction of the middle and upper thirds. The usual treatment of the fractures by splints. A drainage tube was fastened in the wound communicating with the fractured femur, and six Lister dressings applied afterwards. The compound fracture was reduced to a simple fracture by the thirty-fifth day. Temperature was invariably normal. Discharged well on the one hundred and sixtieth day. Reported two months later. Has been acting as night watchman, and without any inconvenience from his injuries. Has no lameness, and walks without support of any kind.

CASE XI. A man, aged twenty, while standing near a rapidly revolving wheel, the edge of which was covered with sand-paper held in place by tacks, suddenly turned his knee toward the wheel, and before he could withdraw it had received a lacerated wound of two and a half inches on the outer border of the patella and opening into the knee-joint. Six hours afterwards he was admitted. The joint was washed out with a one-to-forty solution of carbolic acid and the wound sewed up; no drainage tube inserted; a dressing was applied, and the limb placed upon an excision splint. Dressings changed seven times. Discharged on the seventy-ninth day with excellent motion in the knee-joint. Temperature highest on the third day, 101° F.; during the rest of the time it varied within normal limits.

CASE XII. Incised wound of knee-joint, of three hours' duration, in a man, twenty-four years old. The wound was syringed out with a one-to-forty solution of carbolic acid, the dressing applied, and the leg

bandaged to an excision splint. No pain, tenderness, or swelling. Discharged well on the twenty-fourth day. Temperature normal throughout. No impairment of the motions of the joint.

CASE XIII. A man sixty-five years old. Compound fracture of tibia and fibula at the middle. Fragments wired together. Side splints. Thirty-eight dressings applied. Wire removed on the thirty-ninth day. Reduced to a simple fracture on the one hundred and twentieth day; a firm union. Temperature throughout was within normal limits.

CASE XIV. A man, aged fifty-eight. Compound fracture of the tibia and fibula at the middle. Side splints. Two dressings applied. Reduced to a simple fracture on the fourteenth day. Discharged with a good union on the fiftieth day. Temperature varied between normal limits throughout.

CASE XV. A man, forty-five years old, entered with a comminuted fracture of the tibia and fibula at the middle of both legs from a railroad accident. The fracture of the right leg was compound. The fragments were wired. Two dressings applied. On the seventh day trismus. Chloral, twenty grains, bromide of potassium, thirty grains, given every four hours; after forty-eight hours, doses increased to forty grains of bromide and thirty grains of chloral. Milk punch given freely, it being the only nourishment he would take. On the tenth day opisthotonos and death. Temperature previous to the development of trismus varied between 98.7° and 100° F. Afterwards it was between 103° and 106° F.

CASE XVI. A man, thirty-three years old, entered with a crushed foot from railroad injury. The soft parts were lacerated, and the tarsal, metatarsal, and phalangeal bones comminuted. Amputation at the ankle-joint by Syme's method. Six "phenyle" dressings. On fifteenth day dressing omitted, and a small granulating surface dressed with charpie. Discharged well on the thirtieth day. Union by first intention except at one end of the wound. Temperature for five days after the operation between 99.5° and 101.5° F.; afterwards normal.

CASE XVII. A boy, eleven years old. Two hours before admission his foot had been crushed by a car-wheel. The soft parts were lacerated and bruised, and there was a wound made by the flange of the wheel, laying the foot open from the commissure between the second and third toes nearly to the cuneiform bones, and exposing the sides of the metatarsal bones. The phalanges of the second, third, and fourth toes were fractured. The whole wounded surface was carefully washed with a solution of "phenyle," and dressed with an abundance of gauze. On the following day his temperature was 102° F.; afterwards it varied between normal limits. He was discharged well on the fifty-fourth day, with a useful foot, and without the loss of a toe.

CASE XVIII. A woman, forty-eight years old, with a lipoma of twelve years' growth on her back. It was nodulated, of about the size of a child's head, and located between the scapulae. Incision five inches in length, and the tumor dissected out. Three dressings. Union by first intention. Discharged well on the eighteenth day. Temperature on the first day after the operation 101° F.; following that it ranged between 98° and 100° F.

CASE XIX. Lipoma of the arm in a woman, forty-four years old. It had been growing fifteen years,

was about the size of a man's head, and adherent to the outer side of the arm, between the shoulder and elbow. Excision. Weight thirteen pounds. Three dressings. Last one removed on the fourteenth day, and a small granulating surface left dressed with carbolic cerate. Discharged well on the thirty-fourth day. Temperature on the third day after the operation 102° F.; normal during the rest of the time.

REMARKS BY DR. BEACH.

Admitting all the advantages which the employment of carbolic acid as an antiseptic affords, it must be conceded that enough cases of poisoning have occurred, through its absorption from surgical dressings, to establish beyond question its toxic influence. Mr. Lister recognizes its injurious effects upon some people, and has recently directed attention to the antiseptic qualities of the oil of eucalyptus globulus. The disadvantages of the latter (insolubility in water and rapid evaporation from mixtures containing it) may be corrected in part by a combination with dammar gum, which Mr. Lister has suggested.

As the absorption of carbolic acid from surgical dressings cannot be anticipated in any given case, it becomes a serious question, as to how far surgeons are justified in protecting wounds from septic processes by subjecting patients to the possibility of a fatal result from poisoning.

It will be noticed that in some of the cases reported carbolic acid was replaced in the spray, gauze, and solutions by a new preparation named "phenyle." My attention was called to it more than a year ago, and since then I have used it freely in the hospital wards, supposing that its efficiency as an antiseptic was dependent upon a certain amount of carbolic acid in a crude state, and masked by some other and less active agent. To settle that point, I asked Mr. C. Harrington, 2d, of the Harvard Medical School, to make an analysis, which he has kindly done, with the following result: "*Phenyle* contains 0.79 phenol (carbolic acid) and between eighty and ninety per cent. of a high-boiling tar oil, — probably 'dead oil,' whose most prominent component is naphthaline, and which of itself contains little or no phenol (carbolic acid). The emulsifier is probably a potash soap or something closely allied." So far as I have been able to judge from a limited number of observations, the minute quantity of carbolic acid in "phenyle" is not sufficient to explain its antiseptic properties, which appear equal to those of carbolic acid, more powerful than boracic acid, and are protective for a longer time than thymol. The manufacturers of "phenyle" claim that it is not poisonous, nor is it so costly as carbolic acid. I have not observed any poisonous effects from its use, and in one well marked case of carbolic-acid poisoning, where that dressing had been applied to an extensive granulating surface, the poisonous symptoms disappeared within twelve hours after changing the dressing from carbolic acid to "phenyle," and did not reappear. (See, also, Case III.) The solution for the spray is made sufficiently strong by mixing one part of the "phenyle" with two hundred and fifty of water, but for instruments, hands, and irrigation one part to fifty, or from that to one hundred. It does not irritate the skin of those who use it in operating or dressing. In excisions of the breast and operations of like character I have repeatedly omitted the spray

during the operation, using the "phenyle" solution (one to fifty) for washing out the wound thoroughly, after tying the vessels and before using the sutures, then employing a dressing which for its simplicity commends itself to those of the profession who do not find it convenient to procure the gauze or have it made: Apply the protective as in the regular Lister dressing simply to prevent the cotton from sticking to the edges of the wound; then soak a handful of ordinary cotton waste, cut into bits about an inch long, in the one-to-fifty solution: squeeze dry, and apply it closely to the end of the drainage tube; afterwards, place four layers of cotton batting, previously well soaked in the one-to-fifty solution and squeezed dry, over the wound in the same way as the gauze is usually employed; over all, a layer of dry cotton wadding, in order that the bandage which holds the dressing in place need not compress the chest or other part to such a degree as to make the patient uncomfortable. The cotton wadding should overlap the bunch of cotton waste at least five or six inches in every direction, for thorough protection. The time for changing a dressing may be known by the stain on the bandages from the discharge finding its way to the lowest point. The cotton waste is an important part of the dressing, as it takes the place of the gauze in permitting the discharges to flow from a wound instead of accumulating and burrowing beneath the flaps. The strength of the spray used in making the after-dressings has been one part of the "phenyle" with two hundred and fifty of water.

PUERPERAL CONVULSIONS; MANUAL DILATATION; VERSION.

BY J. FOSTER BUSH, M. D. HARV.

Mrs. D., aged twenty-eight, was first seen by me on January 2, 1881, and had always been well up to that time. She considered herself eight months pregnant, and did not expect to be confined till February. Her health during gestation had been excellent, the only trouble having been constipation of an aggravated character. For dinner, the day before, she had eaten heartily of roast pork, following it up, three hours later, with a liberal supply of pea-soup.

Upon going to bed she seemed in the best of spirits, remarking to her husband, "To-morrow I must see the doctor, and engage him for my confinement."

He states that after the remark concerning her accouchement he fell asleep, and was soon awakened by a noise, which proved to have been caused by his wife, who was on the floor in a convulsion. This was soon repeated, and she had several more before I saw her. They were short in duration, and were regularly repeated at intervals of half an hour.

When first seen there was oedema of both feet and legs, which was accompanied by the same condition of the face and hands, showing that the swelling was constitutional, and not due to pressure. A vaginal examination was made just after the first convulsion I saw her in. The finger could not be introduced through the os. There was resistance, though the parts were softened. Large rectal injections were employed, sinapisms applied to neck and feet, bromide of potassium and chloral hydrate given, but the convulsions still coming on at regular intervals, inhalation of ether was resorted to, but not pushed to complete insensibility.

The convulsions still coming on, Dr. W. L. Richardson was called in consultation. It was now six

hours since the first convulsion. She had had eighteen in all, with gradually lessening intervals. The vagina was hot and dry; the os yielding and admitting the end of the index finger. It was decided to do manual dilatation. In twenty minutes after the commencement of this method the os easily admitted my thumb and fingers, held in the form of a cone, to the second joint, representing a circle with a diameter of two inches. The uterine contractions were forcibly felt, though the patient was under the influence of ether. At this stage, my hands being tired, Dr. Richardson relieved me, and in twenty minutes more he had fully dilated the os.

As the amniotic fluid was escaping with every pain, Dr. Richardson passed his hand well up into the uterus, seized a foot, and turned the child. The body and shoulders were brought down, and the after-coming head delivered with forceps. The secundines, being expelled from the uterus by its contraction, were removed from the vagina by traction.

The whole time occupied in the dilatation of the os, turning the child, applying the forceps, tying the cord, and delivering the placenta was *exactly fifty minutes*, and of this time we considered that fully ten minutes were occupied in turning, applying the forceps, and tying the cord, leaving as the time in which full dilatation took place forty minutes. When we consider that our patient was a primipara it will be seen that the time is one of the quickest on record.

The child, a female, gasped feebly at first, but after flagellation and friction cried lustily; and its being alive after so many convulsions on the part of the mother was both a surprise and a pleasure. Upon subsequent examination the child seemed to be of full term. Upon coming out of the ether the patient had another convulsion, and during the next thirty-six hours she had thirty-nine. At first they came on regularly each half hour, as before delivery. At the end of the seventh hour they came on with greater rapidity, she having seven in the space of an hour. Later, they came on at longer intervals, till they ceased, as before stated, thirty-six hours after labor. The treatment during this time was ether during each convulsion, sinapisms to the neck and feet, snow poultice to the head, bromide of potassium and chloral hydrate, large rectal injections, and croton oil. Two injections, of quarter of a grain each, of pilocarpine were given, free sweating following.

Three hours after delivery the catheter was passed, and two ounces of dark urine were drawn. Upon chemical examination it was found to be loaded with albumen, and under the microscope casts and epithelium cells were seen. The urine was drawn twice more, at intervals of three hours, and the quantity obtained each time was about the same, but twelve hours after labor she voided urine voluntarily.

The quantity gradually increased till the seventh day, when it was found that she passed two quarts.

Shortly after delivery there was considerable flowing; in the course of twenty-four hours it had ceased. Hot applications were made over the lower part of the abdomen, and the flow came on again the latter part of the third day.

This I find has been the usual experience in the same class of cases in the Boston Lying-In Hospital.

The day after the convulsions ceased, there was found to be paralysis of the left arm and leg, and the tongue, when protruded, deviated towards the left.

The third day after the convulsions, when I made my morning visit, she said, "This is the first time I have seen you, doctor. Although you have taken away the power from my left side, I am glad I have my right hand to shake with yours." From this time her recovery was rapid.

The urine continues to contain albumen, but now only a small amount.

The paralysis began to improve on the sixth day, at which time she could move the fingers. Now, a month after the commencement of her convulsions, she has complete use of her limbs, the only trouble being that the left leg gets tired easily, and "feels like giving out."

In the third volume of the Transactions of the American Gynecological Society, Dr. Richardson contributed a paper upon Acute Parenchymatous Nephritis, in which he stated that the *quantity* of urine voided rather than the *quality* is to be taken as a guide, and that when the amount falls below the normal standard we must act accordingly.

The same rule holds good post partum as well as ante partum, and acting upon this principle in the present case, after the first day, treatment was pushed in the direction of making the kidneys more active, and spirits aether nitrosi and cream-of-tartar water were given freely.

During the whole time the pulse never rose above 100, or the temperature above 99.06° F. The ease and rapidity with which dilatation of the os took place is remarkable, and, in order that there may be no question that the parts were *dilated*, not *torn*, I will state that the edges were perfectly smooth, and not abraded in the slightest degree.

TWO CASES OF MALIGNANT DISEASE.

BY URANUS O. B. WINGATE, M. D. DART, WELLESLEY, MASS.

CASE I. SPINDLE-CELLED SARCOMA OF BOTH OVARIES, WITH DEPOSITS OF THE SAME GROWTH IN THE STOMACH.

MRS. L. H., English, was first seen by me on the 9th of November, 1879. I obtained the following brief history: She is thirty-nine years of age; has two children, youngest three years old. She was well till August last, when she had some sickness, with symptoms of pneumonia, followed by much debility. Catamenia, previously regular, appeared twice in August; this never occurred before. Since August no menstruation, but a tumor, apparently connected with the uterus, was discovered. There has been vomiting much of the time, which could be relieved for short periods only by treatment. She has suffered much from "canker" of the lips, tongue, cheeks, and pharynx. This symptom has constituted her chief complaint, and she has thought if this trouble could be remedied she would feel quite well. There has been much prostration. A few weeks ago she had jaundice, which lasted nearly two weeks. There has been very little pain at times in the back. She has been under the care of several physicians, some of whom diagnosed a tumor only, others pregnancy, and some made no statement in regard to her disease. Her last two physicians were irregulars, who informed her that she had been poisoned by her previous attendants, but that they could cure her. They were in company, and saw her together. They commenced treatment by

withdrawing all stimulants on which she had been living, ordered sitz baths, and gave her a mixture largely composed of aloes, which produced from five to eight dejections per day; this of course added greatly to her prostration and discomfort.

Present condition: There is a marked sallow, chlorotic complexion; great prostration; no pain. Complains much of "canker." Pulse 140; temperature 103° F. Tongue clean. Mind clear. She is very anxious to get well. There is a large, hard, and nearly smooth tumor, apparently uterine, occupying the lower pelvis and extending to the umbilicus. The cervix and os uteri appear healthy to the touch. No tumor in the epigastrium or in either hypochondria. There is no edema. No albumen nor casts in urine. Emaciation moderate.

November 12th, patient was seen by Dr. Francis Minot in consultation. Patient had rallied somewhat by use of stimulants; otherwise the same. The tumor was thought to be a uterine fibroid. It was also thought possible, but not probable, that pregnancy existed. Owing to the doubt concerning pregnancy, and the very severe prostration of the patient, it was not thought expedient to attempt a passage of the sound or probe into the uterus at that time.

November 14th. Severe vomiting set in, vomitus consisting of a thin yellowish fluid, not abundant. Nothing could be made to remain on the stomach.

November 15th. Sixth day of my attendance. Still vomiting. Complains of much distress in the stomach; relieved by small doses of morphia. She gradually sank, and died at 7.30 p. m.

Autopsy, forty-six hours after death. Present, Drs. Cowles, Cook, and Kingsbury.

Brain not examined. No diseased condition was found in any organ or part except in the ovaries, pyloric end of stomach, and lungs. These parts, together with the uterus, were removed and forwarded to Dr. E. G. Cutler, who very kindly examined them and sent me the following report: "The left ovary was about the size of the fist; on section it was found to be solid, and to contain one cyst about as large as a cherry. The surface of the section presented a homogeneous grayish appearance, with few blood-vessels. The right ovary was about as large as the head of an adult; on section it was also solid, with three or four small cysts in different parts of the organ. This ovary contained far more blood-vessels than the other, and there was mucoid degeneration of its substance to a limited extent.

"On microscopic examination both ovaries were found to be made up of relatively large spindle and round cells, with enormous oval nuclei, each containing one or more distinct nucleoli lying close together, with a slight amount of intercellular substance, and arranged in bundles or groups. There were many blood-vessels, with rather thin and indistinctly-marked walls. Mucoid degeneration of the right ovary was marked.

"The pyloric end of the stomach was found to be thickened in two distinct places, and on section this thickening was found to be both of the muscular and mucous coats of the stomach, amounting to about three-fourths of an inch or more.

"A microscopic examination showed that this thickening was due to an infiltration of the same sort of tissue as in the ovaries. There was no ulceration of the mucous coat.

"The tumors were sarcoma of the ovaries, and the same of the stomach. Virchow, in his classical work on tumors, figures and describes almost precisely what we saw in our specimens.

"There was limited thickening of the pleura at the apex of each lung, with, at the same time, an increase of interstitial connective tissue. . . . It represented recovery from an old inflammatory process at the apices, probably what is known as catarrh of the apices."

CASE II. MALIGNANT DISEASE OF THE UTERUS, WITH PROBABLY SECONDARY DEPOSITS IN THE STOMACH.¹

Mrs. H. H., American, was first seen by me late in the night of the 13th of September, 1879. She is forty-eight years of age; mother of three children; youngest eighteen years old.

I found the patient suffering from quite a severe pain in the pelvic region extending through to the back. There was also a smart uterine hemorrhage. Patient attributes her trouble to the menopause, stating that her periods have been somewhat irregular for several months past, but the flooding at this time is much more severe than ever before, and she has never had any pain before. She presents a fine, healthy appearance, is quite large and fleshy, and states that she never consulted a physician in her life except at the birth of her children. Her labors were all normal.

A vaginal examination was positively declined.

I prescribed as well as I could under the circumstances, and left the case.

September 27th the husband called at my office, stating that the medicine I prescribed at my visit on the 15th inst. had stopped the hemorrhage, and that the patient seemed quite well, but still complained of some pain at times.

December 16th I was summoned again. Pain and hemorrhage have both increased since my last visit. Patient is very nervous, has a chlorotic complexion; her mind is much disturbed about the death of her youngest son, which occurred some nine months ago. She has never become reconciled to his death.

A vaginal examination was again declined, and I prescribed as before, and on leaving the house stated that I should not call again unless I could examine the patient to my satisfaction, and they must not call me again without that understanding.

January 20, 1880, I was called in great haste, and found the patient in great mental and physical distress. There was alarming hemorrhage; large clots were freely expelled from the vagina, and the bed was saturated with blood. The patient was anxious for an examination, and it was with some difficulty that I prevented her from exposing her person in an unnecessary manner. After turning out the clots I found the cervix much enlarged, and of almost stony hardness, and fixed in the pelvis. The whole uterus was much enlarged. There was an old bilateral laceration of the cervix extending to the vaginal junction. There was no deep ulceration nor crumbling of tissue. The hemorrhage apparently came from the cavity of the uterus. Bimanual palpation showed several nodules at the posterior part of fundus uteri. Strong astringents on cotton packed about the cervix, together with ergot and gallic acid internally, checked the hemorrhage.

¹ This case may in some respects serve as a companion to the one reported in the JOURNAL April 15, 1880.

The pain required one half grain of morphia in suppository per rectum. Patient requests not to be informed if serious trouble exists. From this date to the 6th of February the hæmorrhage was a very troublesome feature in the case. A piece of alum, in size and shape nearly resembling a large glans penis, with a string attached to one end, passed up against the cervix and left for a few hours never failed to arrest the hæmorrhage. On the 6th of February the string became detached from a piece which had been inserted that day, and the nurse being unable to remove it let it remain until the morning of the 7th. I then removed it after some difficulty. The vagina and vulva were very sore and tender for several days, but there was never a return of the hæmorrhage afterwards. Dr. G. J. Townsend saw the case on this day in consultation. Suppositories per rectum containing a half grain of morphia and one third of a grain of extract belladonna relieved the pain.

February 17th. There is obstinate constipation, and also a slight, dark, watery discharge from the vagina, but the odor is not particularly offensive. The discharge lasted only a day or two.

February 20th. Vomiting came on which lasted until the end. It was only relieved by morphia, three fourths of a grain being required per rectum at this time.

March 7th. She is taking a grain of morphia every four hours. Vomits much of the time. Vomitus consists of a dark-greenish fluid without odor. She retains extract beef and champagne only. No tumor can be discovered in epigastrium. The uterus is much enlarged, and presses hard against the bladder and rectum. There is a constant desire to urinate and defecate, and her sufferings from this source, and from severe pain in the left ovarian region extending through to the back, are very great unless constantly under the influence of morphia.

March 10th. Suppositories per rectum in two-grain doses failed to give relief, and the hypodermic method was resorted to, one half grain of sulphate of morphia with one ninetyeth of a grain of sulphate of atropia, giving perfect relief.

April 1st. Five grains of sulphate of morphia required in the twenty-four hours to give relief. Urine has to be drawn with catheter. No motion of bowels could be had without manual assistance. After receiving a dose of morphia she was able to take extract of beef, wine, and champagne quite freely; these seemed to be retained. In about four hours' time, however, vomiting and retching in a most severe form would come on, together with severe pelvic pain, and persist until the morphia was again administered. Occasionally there is a slight, dark, thin, watery discharge from the vagina, which is quite offensive, but does not last more than a day at a time. From April 12th to the time of her death, which occurred April 20th, fourteen grains of sulphate of morphia were required each twenty-four hours to give her relief from pain; this amount was given subcutaneously in four doses. Four days before death she became very maniacal when awaking from the effects of the morphine, her principal maniacal exclamation being, "O God, you have killed him, you have killed him!" her attendants supposing that she referred to the death of her son. On the morning of April 20th I found her quite free from delirium. No morphine had been given for nearly six hours. She expressed herself free from suffering, but

she was pulseless. She soon passed into a quiet sleep, in which condition she died in the evening. No morphine was given, or seemed to be required, for eighteen hours before death. No autopsy could be obtained.

Would not the history of this case, together with the absence of broken-down tissue, etc., lead us to expect spindle-celled sarcoma? It is to be regretted very much that an autopsy could not be obtained in this last case.

If these two cases possessed the same pathological conditions, as in many respects they seem to possess, it seems very interesting to note the very severe suffering in one case, the most severe that I have ever witnessed, requiring my almost constant attendance day and night for several weeks, and demanding the largest doses of morphine I have ever administered, while the other experienced comparatively almost no suffering.

CASE OF ABSCESS OF THE BRAIN FOLLOWING PNEUMONIA.

BY LOUIS BRECHEMIN, M. D.,
Assistant Surgeon United States Army.

PRIVATE John R. Penn, aged twenty-six, was admitted to hospital July 3, 1880, suffering from pneumonia of the lower lobe of the left lung. The case was marked throughout the course of the lung trouble by profuse expectoration. The highest temperature observed, 102.4° F., occurred on the morning of July 7th. From this time the fever gradually subsided, and the physical signs of the lung trouble diminished until a normal temperature was reached on July 13th.

From the 14th to the 17th the patient appeared to be in fair health, and was allowed to walk around the wards. The cough had disappeared entirely, and the only complaint was a want of power in the left arm, and a slight pain in the left shoulder. On the morning of the 18th I was surprised, at my visit, to find that an attack of hemiplegia of the left side had supervened. The paralysis was not marked in the face, but affected the arm and leg. Nausea and vomiting also occurred, but were relieved by appropriate remedies.

The next day the patient complained of a very severe headache, not localized. About ten A. M. an attack of convulsions, lasting ten minutes, occurred.

The case progressed until death took place in the afternoon of July 25th. The symptoms presented up to this time were as follows: paralysis of left arm and leg; no marked changes in the pupils except sluggish reaction to light; left eyeball is turned outward, showing paralysis of internal rectus muscle; no paresis of sensibility in the left side; no aphasia; patient responds fairly to questions asked; pulse slow and full, averaging 48; temperature was 102.4° F. on July 20th, but after that never above 98.6° F. until just before death, when 103.8° F. was recorded.

The post-mortem examination, made nineteen hours after death, gave the following results:—

Brain, marked congestion of membranes and upper surface of right hemisphere; abscess discovered in medullary substance of middle lobe of right hemisphere over right lateral ventricle, containing thick greenish pus, of disagreeable odor, about two and one half ounces in quantity; brain substance in vicinity of abscess softened; slight effusion in right lateral ventricle.

Lungs, hypostatic congestion in both; right lung shows points of caseous degeneration at the apex, also one large calcareous nodule; slight œdema in both.

Heart, soft clot in right side; valves normal.

The post-mortem results in this case, taken in connection with its history, show, I think, that the abscess was of embolic origin, the embolus being conveyed probably from the diseased lung to the brain. An interesting fact is the want of chronicity in the lung symptoms. In most of the previously reported cases of cerebral abscess following pneumonia, the lung trouble had advanced at least to the stage of gray hepatization. Purulent infiltration, in these instances, is quite common. In the present case the post-mortem results found in the lungs were somewhat negative. The amount of congestion in the right lung would not justify a diagnosis of red hepatization. The abscess appeared to be recent, as it did not possess an enveloping capsule; its size was about that of an ordinary hen's egg. It was situated about half-way between the external surface of the right hemisphere and the right lateral ventricle. As will be seen from the previous history, the acute symptoms of the brain trouble set in one week before death.

FORT MEADE, D. T., April 11, 1881.

Recent Literature.

On Anchylosis. By BERNARD E. BRODHURST. London: J. & A. Churchill. 1881. 4th Ed.

A monograph from Mr. Brodhurst upon a subject to which he has devoted so much attention will repay careful reading. Coming, as it now does, with the stamp of a fourth edition, it must be regarded as having already gained the position of an accepted authority.

The writer shows that the procedure of forcible rupture judiciously carried out is almost entirely free from danger of exciting inflammation, or of injury to the limb. He has operated a thousand times, without fracturing the bones or rupture of a blood-vessel. Comparing these figures with those of Nussbaum (32 fractures of the condyles, 7 of the tibia, in 119 cases of forcible straightening of the knee), the conclusion is unavoidable that Mr. Brodhurst's method is the safer, unless the latter is more successful in the selection of his cases. Mr. Brodhurst in rupturing fibrous ankylosis relies entirely on the motion of *flexion*, rejecting extension as dangerous and unnecessary. In some cases he divides subcutaneously the ham-string tendons (in affections of the knee), and the adductor tendons in ankylosis of the hip, and applies extension by a weight for a few days, until the wounds have healed; the patient is then chloroformed and forcible flexion used. In certain cases the hands alone are insufficient, and simple mechanical means are resorted to. Immediately after the operation a gutta percha moulded splint is bandaged to the limb and worn for a few days, after which passive motion is required for a short time. Sometimes two or three sittings are necessary before a complete cure is won. Twenty-five cases are reported to illustrate the success of the method and are sufficient to encourage future attempts, but there is a lack of fullness in the notes, and the reader is left with the suspicion that some may have been the results of periarthritic, rather than arthritic, inflammation.

The chapter on Pathology needs revision, in the light of modern researches. Evidently Mr. Brodhurst is not a pathologist, and has not taken the trouble to follow the teachings of German observers in their study

of joint diseases. "Effusion" of "inflammatory product" and "bands of lymph" are terms not sufficiently precise for the younger generation of students and practitioners. The chapter on Bony Anchylosis is also not so full as would be desirable in a monograph attempting to treat the subject thoroughly. No reference is made to the increased safety of open osteotomy gained by antiseptic operation. And the method of fracture, near the joint, advocated by Billroth, Nussbaum, Stanley, Taylor, Tillaux, and Morton is not mentioned.

The book is not so complete as was Dr. Little's on the same subject, for its day and generation, but it has the merit of being much more recent, and is in every respect a thoroughly useful and sensible treatise.

The Diagnosis of Diseases of the Spinal Cord. An address delivered to the Medical Society of Wolverhampton, October 9, 1879. By W. R. GOWERS, M. D. Second Edition. Philadelphia: Presley Blakiston, 1881. Pp. viii., 86.

This address is well worth reading. The author says in his preface that this second edition "has been carefully revised throughout." A brief review of the medical anatomy of the spinal cord is followed by a section devoted to the physiology of the cord in relation to the symptoms of its diseases. Then follow sections devoted to the diagnosis of the locality of the disease and of the nature of the disease.

Considerable space is devoted to a consideration of the phenomena of "tendon-reflex." He concludes that they are dependent upon a "muscle-reflex" irritability which has nothing to do with the tendons, and the one condition which all have in common is that passive tension is essential for their occurrence. He proposes the name "myotatic contractions."

The foot-clonus is regarded as of great importance for diagnosis, always indicating organic lesion of the cord. He says, "I have seen many such cases, thought to be hysterical, in which it needed but a touch on the sole of the foot to excite such a clonus as is absolute proof of the existence of organic disease."

The description and explanation of the changes in electrical reaction of nerves and muscles is short, intelligible, and satisfactory. When speaking of pain he says: "In organic disease of the bones of the vertebral column it is an almost constant symptom, and is combined with local tenderness." This is rather too sweeping a statement. Discomfort or pain is not unfrequently present, but local tenderness is very often absent.

"A large number of authorities here and abroad are skeptical as to the existence of such a condition as 'reflex paralysis,' that is, a paralysis due to the effect on the centre of some peripheral irritation, disappearing when this was removed. I have never seen a case which seemed to me distinctly such; and although our modern knowledge of the various phenomena of inhibition and reflex action renders such a paralysis *a priori* even probable, it is certain that the theory has been extensively misapplied."

Dr. Gowers is an earnest advocate for a nomenclature which shall express the nature of the lesion and its locality, even if such names may seem rather long; he also advocates the use of plain English names, as "anterior cornual myelitis" instead of "anterior polio myelitis" or "tephro-myelitis."

Medical and Surgical Journal.

THURSDAY, JULY 14, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE CRIME AT WASHINGTON AND ITS LESSON.

IN the absence of exact evidence as to the facts in the case, perhaps it is too early to attempt to measure the responsibility of the poor wretch who has so recently horrified the country by his efforts to assassinate the President. If, however, the reports are substantially correct, that Guiteau's uncle and two cousins were insane, that he was as a boy ill-balanced, and not to be depended upon, as a youth irritable, full of vagaries, and without power of concentration in steady work, as a man possessed with constantly varying extravagant delusions for which there was no sort of reasonable foundation, with a mind always vacillating between several impracticable projects; that he made a homicidal attack upon his sister with an axe several years ago without any real provocation; that he has pursued several women with wild plans of marriage; that he has threatened various persons upon trivial grounds; and finally that he supposed he should do the country a great service, and obey God's direct command if he could succeed in murdering the head of our government,—or even if disappointment, revenge, political illusions, and extreme Conklingism furnished the chief motives for his act, there can be no kind of doubt that he is a lunatic with delusional insanity of so long standing as to have produced very considerable dementia in a mind of originally bad quality. Indeed, we shall be surprised if in twenty or thirty years, if he is alive, he is not quite demented. That the pernicious "spoils system" was even the occasion of Guiteau's insanity is, of course, a theory that cannot be maintained. That it was the unsuccessful scramble for office, as one of the due rewards to the victors in the late political contest, that crazed his unsteady brain to the point of crime, seems not only possible but in the highest degree probable, while few persons will pretend to deny that the fact of the President's being the actual distributor of the spoils to the hungry for office was the immediate cause of his being selected as the victim of the would-be assassin's bullets. These facts carry with them their own moral as regards our civil service, which we hope will be heeded. It is with another view of the question that we are interested as medical men.

Except in the high position of the victim, the widespread disaster likely to arise in case of his death, and the deep significance of the causes of the crime, the attempt to kill President Garfield differs only in un-

important details from events with which we are made almost daily familiar through the newspapers, and which are sure to occur from time to time so long as irresponsible insane persons are allowed to be at liberty. We do not mean to assert that every person having morbid ideas and impulses is from that fact insane, nor that every individual technically insane is thereby necessarily to be considered irresponsible in every respect. Unfortunately for the good of society that doctrine has been already pushed too far when medical experts, not satisfied with their proper duty of stating facts, have, in their endeavors to make out a case, assumed the function of the courts in trying to dictate the course of the law. Those of the insane, too, who commit crimes have for the most part been thought up to that time sane or at least harmless, and the vast majority of them have appeared to the community at large so like other people that physicians are loudly denounced, or not heeded, when they advise their committal to asylums early enough to prevent serious crimes, while, at the same time, the same community is no less loud in its demand for their summary hanging, if they destroy life, whether fully irresponsible or only partly so.

The fact is overlooked that in becoming insane, people do not cease to be men and women, and that they act, within narrower limits of self-guidance and self-control, chiefly like other human beings; that the actions of very many of them are commonly from plan, with motive, premeditated, with more or less clear knowledge of abstract right and wrong, with an understanding of the nature in general of deeds like theirs but incapacity to see the wickedness of their particular act, and that they are guided within certain bounds by considerations of self-interest. Those easily recognized as insane, the very demented and maniacal, are commonly under some sort of control and rarely have opportunities for crime; the others differ from sane people in the extent to which they are controlled by their morbid ideas and impulses, and in the degree of the mastery of their delusions over their reason or will. Such being the case, although there can never be any satisfactory definition of insanity, any absolute criterion of responsibility, or any human means of determining in doubtful cases how far the possible self-control had been exercised, it is difficult to avoid the conclusion that all criminals, sane or insane, should be treated from the standpoint of the safety and good of society. It does no good to hang insane criminals, some of them do not dislike that notoriety, others are not deterred by any penalty, at the same time that many are in their daily conduct more or less amenable to punishment and discipline. The ordinary prison is not wholly the place for the insane of the criminal class and is absolutely unfit for those of previously good character, who commit crimes by virtue of their insanity. The insane asylum is not a safe enough place of custody for the former class, or thoroughly adapted in organization and management for all of the latter, English experience having shown that ten times as many escape without recapture by the end of the year from the asylums as from the criminal asylum at

Broadmoor. We really need separate criminal lunatic asylums, special accommodations in prisons and suitable provision in insane asylums, according to the needs of each particular case.

It rests with us to estimate the mental condition of the criminal insane from as nearly a judicial point of view as is possible; it remains for the legislatures and courts, and not for us, to decide what the protection of society demands. We can, and should, insist upon the prompt committal to proper supervision and control of the insane of manifestly dangerous tendencies who come before us, whether in so doing we are unreasonably blamed or not; we should forbid an insane man's being held to be responsible because he can add, subtract, and multiply, and does not look wild, and we should demand that the state provide proper receptacles for the safe keeping of all lunatics dangerous to society.

Not the least useful lesson to be learned from this miserable affair has been pointed out by our esteemed contemporary, the *Boston Herald*, that there should be less of party and faction where the littleness of the objects contended for is so clearly illustrated; that the President himself, than whom no man knows better what the country needs in the way of reform, should be admonished to take higher grounds—to serve the country with singleness of purpose and to care less for party. If this were done, what would be more natural and right than that public attention should be drawn to the whole unfortunate diseased class to which Guiteau seems to belong, and that we should do them the tardy justice of seeing that not only society shall receive reasonable security from their pitiful acts, but also that they are protected from themselves, in the least rigorous and most humane way possible? When it is fully realized that there is so much room for improving the condition of the insane in our best states, and that in many parts of the land they are wretchedly treated, when the vastness of the problem of the duty of the state to the insane is adequately recognized, when the intimate relations of insanity with our whole social economy is fairly appreciated, the states will no longer delay in giving the matter that attention which its importance demands. There will be a competent expert lunacy commission or commissioner, in some form or other, in every one of our states, as there is in none now. It will be considered as important also, to appoint a United States Commissioner of Insanity, to consider the various questions relating to the treatment of our 100,000 insane, as to have a Commissioner of Agriculture.

THE PRESIDENT'S WOUNDS.

THE attempt upon the life of our Chief Magistrate has given to the subject of gunshot wounds of the abdomen an unusual interest and importance, not only to professional men but to the public at large. The proverbial gravity of this class of injuries is due in part to the ease with which that portion of the body is penetrated by a missile, owing to its comparatively unprotected situation but chiefly to the character of

the contained organs and their highly sensitive covering, the peritoneum. The vascular condition of the viscera and their close proximity to the great blood-vessels renders death from primary hæmorrhage imminent, and their delicate structure favors the production of an amount of laceration which retards the healing process, while the accompanying inflammation, with its attendant dangers, is unusually severe. But the most frequent source of anxiety to the surgeon is the peritoneum. Although modern science has shown us that this membrane is far more tolerant of the operator's knife than had formerly been supposed, it is nevertheless but too easily irritated and inflamed by the presence of foreign bodies, or by the secretions or excretions of the organs which it envelops, the very structures themselves becoming under these circumstances a source of injury to one another. The dangers of peritonitis are largely due to the intimate relation which this membrane maintains with the lymphatic and nervous systems, the pyrogenous material rapidly spreading itself through the economy, producing violent febrile disturbance, or that condition known by some authors as peritonism or collapse establishing itself. It is well to remember in this connection that the temperature varies accordingly as one or the other condition predominates, being at times abnormally low, at others raised above the normal standard. Later, we may have secondary hæmorrhage to contend with, or excessive supuration with all its possibilities.

Of all the viscera the organ which seems to have excited the greatest interest in the present case is the liver.

The prognosis of shot wounds of the liver is stated to be very unfavorable. A glance at the surgical history of the war suffices to show how severe the injury inflicted by a bullet invariably is. Owing to the peculiar consistency of the organ there is always considerable laceration, even though the projectile be a small one. Otis describes the wound as a sort of stellate fracture, not unlike, we should say, to that produced in a pane of glass by a bullet or stone. The great venous sinuses are laid open, and a copious hæmorrhage is the result, which not unfrequently proves fatal. Should the patient escape this danger, he is exposed to the risk of a discharge of bile from the injured gall ducts, which, if the wound communicate with the peritoneal cavity, cannot fail to produce grave complications. It must be said, however, that most shot wounds of the liver which have been reported are combined with other severe injuries to the abdominal organs which may account in part for the great mortality. Otis nevertheless reports fourteen recoveries out of thirty-seven cases, a much more favorable series than other writers have collected. The question is often asked, could the ball be removed from the liver? No such operation is reported during our war, although foreign writers urge an attempt in this direction.

Turning now to the President's case, we may venture, with the data afforded us by the official bulletins, to speculate upon the possibility of an injury to this organ: and firstly, supposing the ball to have penetrated so deeply, it is interesting to recall the anatomical re-

lation of the part near which the wound was inflicted. The bullet, which for a pistol ball is a very large one, — of No. 44 calibre, — is said to have entered between the tenth and eleventh ribs on the right side, three and one half inches from the spine, splintering the edges of the ribs as it passed between them. It so happens that on the posterior aspect of the right lobe of the liver there is an oval space of considerable size left uncovered by peritoneum, owing to the reflection of the upper and lower layers of the coronary ligament; now supposing the ball to have continued onward in its course, it might have entered the liver at this point without touching the peritoneum. That the latter has escaped injury is highly probable, owing to the absence of all symptoms of peritoneal inflammation up to the present time. The primary hæmorrhage does not appear to have been excessive or sufficiently great to have been in any way characteristic of an injury to the liver. The character of the discharge from the wound has at no time been so modified as to suggest an admixture of bile; a slight amount of jaundice has been reported, but this symptom is said to be present only in a small proportion of cases, and so far as we can learn there has been no more than might easily be accounted for in moderate digestive disturbances.

The intercostal space through which the bullet forced its way is far too narrow to permit so large a projectile to pass without meeting with resistance from the ribs, which, as has been stated, were splintered by the ball. When we take into account the ease with which a ball is deflected from its path, there being, in fact, nothing so insignificant that may not influence its course, it is evident that in the present case it might easily have been turned to the right or left. In the latter direction the least possible deviation from its course would have brought it in contact with a large bony prominence, in the spongy tissue of which it would find a comparatively safe and firm lodging-place, the body of one of the dorsal vertebrae. A cross section of the abdomen at this point will show this bone to be the anatomical centre of the body, and amply protected in the direction from which the shot was fired by dense masses of muscles, tendons, and bone. Although the range was extremely close, the charge of powder was a light one, and might easily have exhausted itself upon such obstacles. This would leave the offending body in close contact with the nerve centres, and it is precisely to injury of such structures that one of the most prominent symptoms points, namely, the pain in the feet. Dr. Bliss is stated to have explained this symptom as produced by an injury of one of the sympathetic ganglia which lies directly in the track we have suggested. Had the ball been deflected to the right it would hardly have spent its force until it had penetrated deeply into the abdominal cavity. The theory that it has passed downwards into the pelvis and is in contact with the ischiatic plexus, is of course among the possibilities, for there is no freak of which a bullet is not capable.

The data we have at our command up to the time of writing, we may safely say, give no symptoms of a penetrating wound of the abdominal cavity.

If this be the case, the dangers of the future arise chiefly from the character of the wound itself rather than from the presence of the bullet, which thus far has not shown that it is not securely imbedded in a place of comparative safety. The tortuous shape of gunshot wounds and their contused surfaces are often to blame for difficulties which it is common to ascribe to the missile. By good drainage and antiseptic treatment these may be happily surmounted.

We have nothing but praise for the judicious manner in which the illustrious patient has been treated, and commend strongly the good judgment which refrained from making a meddlesome hunt after the ball. It would be difficult indeed to find anywhere better advisers for such an emergency than those in our national capital, whom the rich experiences of our late war have peculiarly well fitted for such a grave and important task.

MEDICAL NOTES.

— Dr. Charles P. Lyman's report to the Department of Agriculture on Contagious Pleuro-Pneumonia, illustrated with some very handsome colored lithocautic plates of diseased portions of lung of American cattle brought back from Liverpool by Dr. Lyman and examined microscopically by Dr. W. F. Whitney, of Boston, is an interesting document. It shows that the frequency of the disease in question among American cattle landed in Liverpool has been greatly exaggerated.

— The *Philadelphia Medical Times* thinks that few of those who furnish the "printer's devil" with medical copy get paid for their labor, but the great bulk of this, in the aggregate, gigantic mass of toil is either paid for not at all, or with such a pittance as not to be worth naming. Nevertheless the avalanche grows constantly. In this country alone the yearly output is by tons. Using the *Index Medicus* as a guide, we find that in the world last year eleven thousand seven hundred doctors thought they had something new to say, or some new way of saying something old. Mostly were they moved by vanity, and surely the outcome is vexation of spirit.

What the end of all this is to be is not easy to perceive. In fifty years more, if things go on, our unfortunate descendants may witness twenty thousand doctors, with vehement haste, yearly urging their pens in eager rivalry for fortune.

— The following is copied by the *Philadelphia Medical Times* from the *Réveil Médical*, which contains a picture of the monstrosity it describes:—

The *Wiener Med. Presse* contains an account of the brothers Tocci, born near Turin in 1877. These creatures have two heads, two pairs of arms, and a double thorax with independent thoracic organs. From the sixth rib down, however, they have one body in common, a single abdomen, a single umbilicus, one anus, one right leg, and one left leg. The genital organs comprise a penis and scrotum, but the rudiments of a second masculine genital organ can be discovered posteriorly, which occasionally permits a

small portion of urine to escape. Viewed from behind, there are two separate vertebral columns, two sacrums, and three buttocks, of which the middle one is merely the result of union of the other two, and contains a rudimentary anus. One anus serves both infants. The right leg is under the control of one twin, and the left, which is clubbed, of the other. Though well and strong, they cannot walk on this account. The personality of each infant is distinct; one cries or sleeps while the other may laugh or be awake. They are gay and lively with each other and with strangers. The heads usually lean one to the left the other to the right, but one at a time may place the head in a perpendicular position, provided the other leans over a little more horizontally.

—There has been much discussion recently concerning the stated objection of certain sisterhood nursing associations to send nurses to small-pox cases. Mr. Lewis Wingfield has written strongly to the papers on the subject, and the *Gentleman's Magazine*, in commenting on his published letters, observes that "not the least serious question opened out by Mr. Wingfield's letter is that of the value of our nursing sisterhoods. One and all of these to whom Mr. Wingfield applied declined to send a nurse to serve in a house in which there was small-pox. I do not deny that a woman may well hesitate to face the risk of so serious and loathsome a disease. For those, however, who, in the profession of religion, have formed a sisterhood, to decline such a call is like a soldier refusing to join a forlorn hope. They may be volunteers. That, however, does nothing to free them from responsibility. Fancy our volunteer soldiers refusing, on account of the danger, to front an enemy when he had once landed! I hope this refusal to face danger will open men's eyes to the real value of not a few of the institutions in which women play at being nurses. In our hospitals the presence of lady nurses is not an unmixed blessing. I have spoken to patients who have felt the weariness and suffering of life in hospital augmented by the fact that they dared not ask ladies of gentle birth for the menial service they required. Though less brutal in language, moreover, than the nurse of former times, the lady nurse knows how to make the patient wince when he has the misfortune to get into her black books. We are in a curious transition stage in many matters. When we have settled down to the new order of things we shall find that in nursing, as in other matters, professional service is better than amateur, and shall learn that the sufferer is as often pained as cheered by ministrations that not seldom owe their origin to forms of mysticism, fanaticism, or hysteria. — *British Medical Journal*.

—According to the *Boston Herald* a girl died in Springfield recently from brain disease, and the attending physician has returned, as the first cause of her death, "the graded school system;" second, meningitis.

—About a year ago the *JOURNAL* contained an editorial upon the Production of Sex at Will, based upon the theory and experiments with cattle of Capt. D. D. Fiquet, of Houston, Texas. A recent copy of the *Houston Daily Post* contains letters from other

stock raisers giving the favorable results of their experiments in breeding according to Mr. Fiquet's rules.

—The Canada Medical Association will hold its next meeting at Halifax, Nova Scotia, on Wednesday, August 3d.

—Dr. Gérard Marchant, director of the Lunatic Asylum at Toulouse, died on June 21st, in consequence of being shot with a pistol by an insane patient under his charge.

—According to the *British Medical Journal* the Shetland Islands are not oversupplied with doctors. Excluding the burgh of Lerwick there are six medical men to minister to the wants of a population of twenty-seven thousand.

—A new organ of the anti-vivisectionists has appeared in London called the *Zoophilist*. The first number contains a good deal of trash, among which is a complimentary notice of a very scurvy article on the Medical Profession and its Morality in England. This article appeared in the *Modern Review*, and was criticised as it deserved to be by the *Lancet*.

NEW YORK.

—Dr. F. R. S. Drake has been appointed clinical professor of practical medicine in the University Medical School. He had previously been lecturer on semeiology, and will now conduct a portion of the clinics hitherto held by Professor Loomis.

Miscellany.

PREVENTION OF HEAT-STROKE.

THE *British Medical Journal* gives an analysis, from the Army Sanitary Regulations of Germany (Kriegs-Sanitäts-Ordnung), of the directions concerning the prevention of heat-stroke among troops on the march. These directions have evidently been framed from experience and a careful consideration of the whole subject and its bearings, and though intended specially for military men are equally instructive to civilian physicians. The instructions are given under the five following sectional headings: General Remarks, Causes, Symptoms, Prevention, and Treatment.

General Remarks. The attention and activity of surgeons ought to increase in proportion to the efforts demanded from soldiers during a march, especially if the march is taking place in a heated atmosphere, for it is then that cases of heat-stroke are imminent. As a matter of diagnosis heat-stroke is to be distinguished from sun-stroke. The effects of sun-stroke, which, in tropical climates, may induce meningitis and encephalitis, in European climates are limited to inflammatory conditions and blistering of the skin of the parts of the body exposed to the solar rays. Heat-stroke is a far more serious and dangerous condition. It is a malady which, in certain circumstances, under the influence of great heat, with a clouded sky as well as in clear weather, is developed very rapidly, and one which, unless opportune assistance is afforded, may lead to death, sometimes within a few hours, sometimes after days have elapsed. Every officer directing the movements of troops ought to understand the causes of heat-stroke, as the disease is a preventable one.

Causes. Among the conditions which favor the production of heat-stroke are the following: (a.) An elevated external temperature, especially when the air is muggy; that is, when it is charged with a large quantity of watery vapor, and there is no wind, so that perspiration does not evaporate, and, consequently, the natural process for cooling the body is interrupted; (b.) Physical efforts, which induce an elevation of the internal temperature of the body; (c.) Deficiency of water, that is, the absence of one of the most natural of the internal means of bodily refrigeration, on which depends the preservation of a due proportion of water in the blood and the supply of the materials necessary for transpiration; and (d.) Insufficient ventilation of the column of men on the march.

Besides the above causes, there are a number of influences, the concurrence of which favor the invasion of heat-stroke. Such are: a want of the habit of marching; a constitution too weak for much exertion; anterior fatigue or illness; insufficient sleep; excesses; and, above all, indulgence in alcoholic drink.

It may be readily understood that at a time of great heat and under other external circumstances the appointed means of regulating the temperature of the body, and maintaining it at a constantly even degree, become insufficient for troops marching on foot in close ranks, particularly when the marches are made, as they often are, during the warmest hours of the day. The sweat, in close weather, cannot evaporate sufficiently; it collects on the face, on the chest, and flows over the body. This is the first refrigerant which fails. If, further, the soldier has not the means of drinking frequently to cool the body and restore to the blood the water abstracted from it by transpiration, if the production of heat continues as a result of the muscular efforts of the march, it may happen, on the one hand, that the blood becomes thickened, and the tissues dry and impaired; on the other hand, that the bodily temperature attains a degree dangerous to life. The man is then struck by heat-stroke. The two other regulators of the temperature, respiration and circulation, are not then sufficient for cooling the body; they become disordered under the influence of the extreme heat of the bodily economy, and in the end paralysis of the heart ensues.

To these causes must be added, when soldiers march in close order in calm weather, the vitiation of the air in which the column moves. Every one who has marched with troops knows what a fetid condition the air attains in warm weather, when there is not a strong wind to remove it fast enough and renew it sufficiently.

Among cavalry soldiers heat-stroke happens more rarely than with infantry, because the muscular efforts, and, therefore, the elevation of temperature, are less with them, and because they move at wider distances apart than men marching on foot.

Symptoms. — The premonitory symptoms of heat-stroke are the following: The perspiration is abundant on the surface of the body, yet the pulse is rapid, the respiration hurried, and the heart beats violently. The soldier feels his head hot, as well as his skin; he has a sense of constriction at the chest; a feeling of faintness; his tongue is dry, his hands swollen, and his face turgid or scarlet; his limbs totter. If at this time a man falls out of the ranks, he will generally soon be restored on being relieved from the pressure of his uniform and accoutrements, by exposure to fresh air, by having some water given to him to drink, and by

applying a wet handkerchief to his head and chest. But if this help be not afforded, and he drags himself painfully onwards, the transpiration becomes exhausted, the skin becomes dry, the lips glued together, the heart beats more feebly and more quickly, the respiration becomes more superficial, and at last the man loses sense and falls, sometimes as if in a fit, sometimes even with the signs of having become suddenly insane. When the condition has reached this degree, death is certain, unless help be afforded. Occasionally, the group of symptoms of heat-stroke are different, and depend on congestive determinations towards the brain, the lungs, or other organs, according to circumstances.

Prevention. — Soldiers the most habituated to marching cannot prevent their bodies from becoming overheated under certain circumstances. The natural remedy for this condition is drinking water. The belief that swallowing water is hurtful when the body is heated arises from prejudice. Of course, some precautions must be used if the liquid is very cold. It is important not to swallow a large quantity at a draught; it is better to drink more often and less at a time, and to mix with the water a little vinegar, tea, or coffee. To wait long that the body may become cool is useless; a few minutes suffice. The wooden water-bottles with narrow throats which soldiers usually carry answer all the purpose required. If circumstances permit, it is important at periods when, after the morning, the temperature reaches 77° F. in the shade, to arrange the march so that part of it may be accomplished by eight or nine o'clock A. M., the men reaching a halting-place at that time; the rest of the march can be taken late in the afternoon or evening. Before quitting a cantonment or halting-place, it should be seen that the water-bottles are filled. Spirits should be avoided. When the soil is sandy, or the roads dusty, it is well to march in as open ranks as possible. Halts should be multiplied and prolonged in airy places as far as practicable. Other points have to be attended to in time of war, but need not be described now.

Treatment. — When a man is attacked by heat-stroke, he should, pending the arrival of a surgeon, be carried to as cool and shady a place as possible; his clothes and accoutrements should be unfastened; his head raised; and care should be taken that he is surrounded as little as possible by people, who would prevent the access of pure air. Cold should be applied, by means of wet towels, to the face and chest, and if this be not sufficient, cold affusions, especially over the trunk, should be had recourse to. The man should be made to swallow water freely, only a small quantity being given at a time. When respiration appears to be nearly arrested, artificial respiration should be proceeded with in the usual way. This should be continued, if natural respiration fails to be quickly re-established, until the arrival of the medical officer. Air should be constantly conducted to the sick man while these means of restoration are in progress. Friction of the palms of the hands, and of the soles of the feet, and other means of stimulating the circulation, are advantageous. Drowsiness should excite mistrust; sleep should be watched with much care. In case of hæmorrhage occurring, the man's comrades should abstain from all stimulating or exciting applications, and merely attend to the general measures above mentioned until the arrival of the medical officer, who will then give whatever directions the particular circumstances of the case may call for.

CRIMINAL LUNATICS.

THE following, which travels back from England, like the Americo-English Stilton cheese, in the columns of the *Medical Times and Gazette*, is not inappropriate at the present moment or to this issue of the JOURNAL:—

"A strong feeling seems to be growing up in the United States against the practice almost universally prevalent there, and which, indeed, still prevails to a considerable extent in this country, of mingling the criminal with the non-criminal insane in the wards of lunatic asylums. This feeling finds vigorous expression in the Report of the Managers of the New Jersey State Asylum, which has just been transmitted to England. With a force and freedom of language unusual in formal official documents in Europe, they inveigh against the objectionable arrangement. 'To place insane convicts,' they say, 'in the same institution and the same apartments with insane patients from the families of our best citizens is inconsistent with every dictate of propriety. The very proposition excites a feeling of revulsion in every bosom. Think of the children of our late governor (honored as he was while living) thrown together in the same section of the asylum with convicts from the state prison! A voice from the tomb of the distinguished dead cries out in condemnation of such an arrangement. And the voice of the living echoes the sentiment, and cries out against the law that requires it. Who is responsible for this? The superintendent does the best he can under the law. The board of managers have again and again directed attention to it and urged a remedy. Governor Parker called the attention of the legislature to it in his message in 1875. Governor Bell, in equally strong terms, presented the matter in his message of 1877. The Senate passed a bill providing a remedy, but it slumbered in the lap of the committee of the House. The evil continues and increases. Let it be removed. Cannot a wing for insane convicts be provided in connection with the state prison? If this cannot be done, a separate building sufficiently secure and suitable for the purpose should be erected for their accommodation. The problem is one that must be solved sooner or later. Let it be done without delay. In our judgment the purity of the institution demands it. Public policy demands it. The ends of justice require it. The good name of the State calls for it. The legislature that meets the case and provides a proper remedy will receive the grateful acknowledgments of the entire constituency of the State of New Jersey.' The medical superintendent of the asylum follows in the wake of the board of managers, and in somewhat calmer accents and more argumentative strain enforces the same theme. He points out that an ordinary lunatic hospital is not constructed in such a manner as to render it suitable for the detention of persons who add determined criminal propensities to insanity, and that it would destroy its hospital character to adapt it to that class, and he pleads for the erection of a separate asylum, meeting the requirements of security, and so organized as to supply humane treatment to the really insane without creating any incentive to convicts to feign insanity. We commend his observations, as well as the more oratorical and uncompromising remarks of the board of managers, to the consideration of that mixed departmental and parliamentary committee which has

been deliberating for at least twelve months on all questions bearing on criminal lunacy in this country. If we might adopt the figure of the New Jersey board of managers, we should say that they have allowed the subject to slumber in their lap, and that their report is awaited, if not with impatience, yet with a conviction that it is slightly overdue. The questions involved in the reference to the committee are doubtless somewhat complex and difficult, but the information which is to serve as the basis of the answers returned to them ought to be readily accessible.

THE INFLUENCE OF LIGHT ON ANTS.

SOME recent researches of Sir John Lubbock upon the influence of light on ants are referred to in the following from the *Medical Press and Circular*:—

The indefatigable researches of Sir John Lubbock have made the features of ant economy all but thoroughly familiar to the great number of working naturalists at home and abroad, and so well is his claim identified with discoveries in connection with these little animals that the scientific zoölogist unconsciously associates all the knowledge of them he possesses with Sir John's name. In a long series of papers read at intervals before the Linnean Society of London, and dealing with the subject of ants, Sir John Lubbock has done very much to clear up doubtful points in comparative physiology and psychology; in many ways, too, the suggestions associated with his conclusions have assisted towards awakening the spirit of research in other and younger minds, a result to be very much desired. The latest contribution from Sir John Lubbock, read on Thursday last, deals with the influence of light on ants. He satisfied himself that the different rays of the spectrum act on them in a different manner from that in which they affect us; for instance, that ants are specially sensitive to the violet ray. If an ant's nest be disturbed the ants soon carry their grubs and chrysalises under ground again to a place of safety. Sir John, availing himself of this habit, placed some ants with larvæ and pupæ between two plates of glass about an eighth of an inch apart, a distance which leaves just room enough for the ants to move about freely. He found that if he covered over part of the glass with any opaque substance the young were always carried into the part thus darkened, and that if he placed side by side a pale-yellow glass and one of deep violet the young were always carried under the former, showing that though the light yellow was much more transparent to our eyes, it was, on the contrary, much less so to the ants. From this point he further proceeded to test the effect on them of ultra-violet rays, which to human eyes are invisible. For this purpose he covered certain nests in two parts, one with violet glass, the other with a flat bottle containing sulphate of quinine and bisulphide of carbon, both highly diathermic bodies. In every case larvæ were carried to beneath the clear coverings, the dark violet portion being carefully shunned. Again, he threw a spectrum into a similar nest, and found that if the ants had to choose between placing their young in the ultra-violet rays or in the red, they preferred the latter. He infers, therefore, that the ants perceive the ultra-violet rays, which to our eyes are quite invisible. But every one will not quite follow the implied conclusion that these rays are necessarily experienced as

rays of light, an assumption urged by Sir John Lubbock, who speculates on the probability of the mixed colors presenting other than the white familiar to human eyes. The experiments are not yet by any means completely described, but so far they have a

high degree of interest for the physiologist, and there can be little doubt that, difficult though it may be to exactly define its direction, the influence of such inquiry is beneficial not to science simply, but also to progress in its practical application in medicine.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 2, 1881.

Deaths reported 3363; 1802 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1262; diarrhoeal diseases 743, consumption 360, lung diseases 211, diphtheria and croup 162, scarlet fever 105, small-pox 46, measles 42, cerebro-spinal meningitis 20, malarial fevers 33, whooping-cough 29, typhoid fever 28, puerperal fever 18, erysipelas 12, typhus fever four. From *small-pox*, Philadelphia 18, New York 16, Chicago nine, Pittsburgh two, Brooklyn one. From *measles*, New York 17, Cincinnati six, Chicago four, Pittsburgh three, Boston, Baltimore, and Newton two, Philadelphia, Brooklyn, St. Louis, New Orleans, Providence, and Nashville one. From *cerebro-spinal meningitis*, Chicago 11, New York six, Pittsburgh four, St. Louis and Cincinnati three, Baltimore, New Orleans, and Worcester two, Philadelphia, Boston, District of Columbia, Buffalo, Milwaukee, Newburyport, and Woburn one. From *malarial fevers*, New York 11, New Orleans nine, St. Louis four, Brooklyn and Chicago two, Philadelphia, Baltimore, Cincinnati, Buffalo, and Chelsea one. From *whooping-cough*, New York and Brooklyn five, St. Louis four, Chicago three, Philadelphia, Baltimore, Cincinnati, Pittsburgh, and Buffalo two, Providence and New Bedford one. From *typhoid fever*, New York nine, Chicago five, Philadelphia four, Baltimore and Pittsburgh two, Brooklyn, Boston, Cincinnati, New Haven, Nashville, and Attleborough one. From *puerperal fever*, New York six, Chicago four, Lynn two, Philadelphia, St. Louis, District of Columbia, Milwaukee, Springfield, and Bridgewater one. From *erysipelas*, New York five, Brooklyn,

Chicago, Cincinnati, New Orleans, New Haven, Charleston, and Taunton one. From *typhus fever*, New York two, Philadelphia and Brooklyn one.

Eighteen cases of small-pox were reported in Brooklyn, one in Boston, 16 in Pittsburgh, one in Buffalo; diphtheria 49, scarlet fever nine, in Boston; scarlet fever 12, diphtheria five, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,033,718 (population of the State 1,783,086), the total death-rate for the week was 17.00, against 15.64 and 18.24 for the previous two weeks.

For the week ending June 11th in 149 German cities and towns, with an estimated population of 7,862,668, the death-rate was 26.4. Deaths reported 3994; 1983 under five: pulmonary consumption 571, diarrhoeal diseases 456, acute diseases of the respiratory organs, 420, diphtheria and croup 126, scarlet fever 81, measles and röteln 43, typhoid fever 42, whooping-cough 38, puerperal fever 22, typhus fever (Königsberg four, Posen three, Thorn two, Tilsit, Halle one) 11, small-pox (Zittau three, Berlin, Munich, Aix-la-Chapelle two, Königsberg one) 10. The death-rates ranged from 16.1 in Hanover to 39.3 in Strasburg; Königsberg 33.9; Breslau 36.1; Munich 31.9; Dresden 23.1; Berlin 31; Leipzig 18.9; Hamburg 22.6; Bremen 27.8; Cologne 27.7; Frankfurt 22.4.

For the week ending June 18th, in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 19.5. Deaths reported 2839: acute diseases of the respiratory organs (London) 225, measles 100, small-pox (London 82) 85, whoop-

ing-cough 81, scarlet fever 73, diarrhoea 67, fever 30, diphtheria 23. The death-rates ranged from 15.4 in Bristol to 27.7 in Plymouth; Brighton 18.8; London 19.1; Leeds 17.1; Birmingham 17.9; Manchester 21.6; Liverpool 24; Sheffield 19.5. In Edinburgh 26.6; Glasgow 22.6.

In the 21 chief towns of Switzerland, for the week ending June 18th, population 479,934, there were 23 deaths from diarrhoeal

diseases, acute diseases of the respiratory organs 14, measles 11, typhoid fever eight, whooping-cough five, diphtheria four, small-pox three, puerperal fever one. The death-rates were: Geneva 11.4; Zurich 25; Basle 28.5; Berne 21.1; St. Imier 36.3; Herisau 46.7.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, APRIL 1, 1881, TO JUNE 30, 1881.

BAILHACHE, P. H., surgeon. Detailed as chairman, board of examiners. April 5, 1881.

WYMAN, WALTER, surgeon. Detailed for temporary duty as medical officer, revenue bark Chase. May 31, 1881.

LONG, W. H., surgeon. Detailed as member, board of examiners. April 5, 1881.

MURRAY, R. D., surgeon. To proceed to Memphis, Tenn., assume charge of the service at that port, and inspect the service at Vicksburg, Miss. April 8, 1881.

FRYLANDER, GEORGE, surgeon. Detailed as recorder, board of examiners. April 5, 1881. To proceed to Richmond, Va., as inspector. April 30, 1881. Detailed as chairman, board of survey, to examine applicants for admission to the revenue marine service. May 10, 1881.

DOERING, E. J., surgeon. Granted leave of absence for thirty days from April 21, 1881. April 2, 1881.

AUSTIN, H. W., surgeon. Granted leave of absence for thirty days from May 5, 1881. April 2, 1881.

GASSAWAY, J. M., passed assistant surgeon. To proceed to Philadelphia, Pa., and assume charge of the service, relieving Passed Assistant Surgeon Stoner. April 7, 1881.

SMITH, HENRY, passed assistant surgeon. To report to chairman, board of examiners. April 25, 1881.

STONER, G. W., passed assistant surgeon. To proceed to Portland, Maine, and assume charge of the service, relieving Surgeon Doering. April 7, 1881.

FISHER, J. C., passed assistant surgeon. Detailed as recorder, board of survey, to examine applicants for admission to the revenue marine service. May 10, 1881.

WHEELER, W. A., assistant surgeon. Granted leave of absence for thirty days (he providing a substitute) from July 7, 1881. June 23, 1881.

CARMICHAEL, D. A., assistant surgeon. To proceed to New York, N. Y., and report to Surgeon Fessenden for duty. April 7, 1881.

RESIGNATION. — DOERING, E. J., surgeon. Resignation accepted by the secretary of the treasury, to take effect May 20, 1881. April 2, 1881.

PROMOTION. — GASSAWAY, J. M., surgeon. Promoted to be surgeon from May 21, 1881. May 16, 1881.

BOOKS AND PAMPHLETS RECEIVED. — A Text-Book of Practical Histology, with Outline Plates. By William Stirling, M. D., Regius Professor of the Institutes of Medicine in the University of Aberdeen. With thirty Outline Plates, one Colored Plate, and twenty-seven Wood Engravings. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1881. (A. Williams & Co.)

A Practical Treatise on Impotence, Sterility, and Allied Disorders of the Male Sexual Organs. By Samuel W. Gross, M. D. With sixteen Illustrations. Philadelphia: Henry C. Lea's Son & Co. 1881. (A. Williams & Co.)

The Study of Human Anatomy, Historically and Legally Considered. By Edward Mussey Hartwell, M. A., Fellow of the Johns Hopkins University.

Pubblicazioni Del R. Istituto di Studi Superiori Pratici e di Perfezionamento in Firenze. Sezione di Medicina e Chirurgia.

Del Processo Morboso del Colera Asiatico del suo stadio di Morte apparente e della legge Matematica da cui e regolato. Memoria del Dott. Filippo Pacini.

Tavole per una "Anatomia delle piante Aquatiche" opera rimasta incompiuta di Filippo Parlatore.

Il Primo Anno della Clinica Ostetrica diretta dal Prof. Cav. Vincenzo Balocchi nella Nuova Maternità di Firenze rendiconto del Dott. Ernesto Grassi.

Lectures.

CLINICAL LECTURE ON HEMIPLEGIC EPILEPSY.

BY EDWARD C. SEGUIN, M. D.

Clinical Professor of Diseases of the Mind and Nervous System in the College of Physicians and Surgeons, New York.

GENTLEMEN, — The case to which I invite your attention particularly to-day is that of a private patient of mine, who has very kindly consented to come before you in order that you may have the opportunity of practically investigating the remarkable disease of which he is the subject.

He is twenty-four years of age, and a cigar-maker by occupation. He always enjoyed good health up to January, 1877, when he had what he describes as a slight fever, which lasted five or six days. When he recovered from this, he found that there was some loss of power in both the upper and lower extremity on the left side, which interfered with his dressing himself and performing various other ordinary actions. In a few weeks after this he was attacked with a spasm, confined, he says, exclusively to the left side of the body, in which he fell to the ground and bit his tongue; while he remained unconscious for fifteen minutes. One month later he had a second similar attack, and for nearly a year afterward he continued to have them at varying intervals and of greater or less severity. Then for a whole year, during which he was all the time under treatment, he remained entirely free from them. In March, 1879, however, the attacks returned, and during that month he had three; while in the following month he had two, the last one that he has had occurring on the 13th of April (more than a month ago, you will perceive).

On questioning him more particularly in regard to the seizures from which he has suffered, we find that some of them were not accompanied by loss of consciousness; and that while they all commenced in a spasm of the left hand and arm, the lightest of them proceeded no further than this. When he first came under observation there was no facial paralysis, no anæsthesia of the left hand, and no tendon-reflex at either knee. The left arm was decidedly paretic; so that, while the dynamometer reached forty and forty-five under the pressure of the right hand, it indicated only twenty and twenty-three under that of the left. As to the ætiology, no cause whatever could be assigned for the affection. It is true that eleven years before the commencement of his trouble he says that he had a chancre, but he is positive that it was never followed by any constitutional symptoms. Moreover, at the beginning of the attacks mentioned he was treated with mercury and iodide of potassium; but without any benefit whatever. When he came under my care, I ordered him thirty grains of the bromides of ammonium and potassium (each dose containing ten grains of the one and twenty of the other,) every night and morning. In addition, he was to wear a sort of bracelet on the left arm, which he could quickly tighten whenever he felt a spasm coming on, and was also to carry in his pocket a small bottle of nitrite of amyl for inhalation at the same time. These precautions, I am glad to say, have already proved of service. On the third of May he had a slight attack, which was promptly checked by the employment of the above means as directed. Since this, however, he says that his left hand has felt somewhat

weaker than it did before; and on investigation I find that it is chiefly the long flexor muscles that are paretic.

In order to fix them more clearly in your minds, I will now set down the principal features of the case upon the blackboard.

In January, 1877, the patient had an illness lasting five or six days which he describes as a "slight fever," and this was followed immediately by partial left hemiplegia, accompanied with paresis on that side and general nervousness. He gradually recovered from this condition; but in a few weeks a peculiar form of epilepsy (which is known technically as hemiplegic epilepsy) appeared. This variety, I may mention, is supposed to be rare; but I believe it is only relatively so. His attacks always commenced in spasm of the thumb and fingers of the left hand, and several times they were accompanied with complete loss of consciousness and biting of the tongue. Others were of less severity; there being more or less marked spasm of the hand, arm, and face, but no unconsciousness, and there have been other attacks still, in which there was a momentary, flash-like sensation in the arm, such as is characterized under the term of simple aura.

Let us next examine a little into his present condition:—

He is a man of perfectly healthy general appearance, as you notice, and when he walks you see that he swings both shoulders evenly, while he has nothing whatever like a paraplegic gait. He would seem, therefore, to have full control of the left lower extremity. His eye-sight is good, and, I believe, has never been affected, except that he has at times had transient diplopia. His memory, he says, is weak. When he stretches out his hands before him, we find that he cannot practice hyper-extension of the fingers of the left one, and, indeed, cannot bring them quite to the horizontal position. When he lifts the left hand to the nose, it is seen that there is some hesitation about the action, but not the movement from side to side which, as a rule, characterizes ataxic movements.

To-day the dynamometer registers forty-seven and forty-seven for the right hand, and twenty-two and twenty-seven for the left. The naso-labial creases and all the other facial lines appear to be very much the same on the two sides; and the tongue does not deviate in the slightest degree when it is protruded. The pupils are observed to be normal, and the patient converges well. When the æsthesiometer is employed for testing the sensibility of the two hands, it is found to be remarkably fine in both, there certainly being no impairment of it in the left. The same is true in regard to the two sides of the head and face. Tendon-reflex, as was previously the case, is as completely absent at both knees, as in instances of tabes; and this is a singular fact, since it is in violation of the general law that in cerebral cases tendon-reflex is increased.

To sum up the prominent points of the examination on the black-board, we find that there is no facial paralysis or anæsthesia, that the left hand is paretic and numb, but characterized by no anæsthesia, that there is a slight ataxiform tendency in the movements of the left upper extremity, that there is a complete absence of tendon-reflex on both sides, that the heart is normal, and that the memory is feeble. Here you observe is a hemiplegic epilepsy, following a partial hemiplegia; its manifestations being true epileptiform attacks and constituting both a limited epilepsy and a motor epilepsy.

Before entering into a consideration of the nature and location of the lesion that is probably present in this patient, let me relate to you a short account of another somewhat similar case, which also occurred in my private practice. In 1868 a gentleman, then thirty years of age, began to lose strength and suffer from dyspepsia; in consequence of which he was sent to Europe for a change of air and scene. While staying in Paris he was troubled with localized tonic and clonic spasms, which lasted only a few seconds at a time, and during which there was no loss of consciousness. At first he made light of these attacks and laughed at them when they occurred; but after a time they became more severe, and he finally began to suffer from *grand mal*. Strange to say, however, he has never had a single true epileptic seizure since 1869, until the present year; although most of the intervening time he has been entirely without treatment. Nevertheless he has had, and still continues to have, one or more slight spasms, of brief duration, every day; and there is considerable numbness about the hand. Occasionally they are more serious, and sometimes the hand is jerked up against the sternum with some violence. The last fit of *grand mal* mentioned occurred in January, 1879; when an unusually severe attack of spasm ended in unconsciousness. Since then there has been no return of the same trouble. His former attacks were accompanied by more or less suffusion of the conjunctiva, and at present the only objective symptom is a slight amount of congestion about the eyes.

About six weeks ago I presented to you a patient suffering from hemiplegic epilepsy; and altogether I have seen a great many cases of this disease. In only one of them was I able to obtain an autopsy; but other observers have been more fortunate, and at present we believe that a satisfactory anatomical and physiological basis has been established for the localization of any lesion giving rise to the characteristic phenomena of the disease. Our knowledge in regard to the subject has been acquired principally since Ferrier's researches upon the cortex of the brain, made in 1872 and 1873; but long before this another Englishman, Hughlings Jackson, from his clinical studies propounded the hypothesis that hemiplegic epilepsy and localized epilepsy were due to lesions situated in the cortex. Ferrier, indeed, has frankly acknowledged that he was indebted to this observer for the suggestion of making the series of experiments whose results have proved so brilliant and so important. Other investigators besides him have also demonstrated conclusively that movements of the face, lips, tongue, and both the upper and lower extremities are intimately associated with the cortex.

By means of a rough diagram on the black-board I will now endeavor to indicate to you some of the more important points that have thus been established. Having represented one of the hemispheres on the board, I draw a line from the fissure of Sylvius to that of Rolando, it will pass through the centre of the motor tract of the cortex, which may be supposed to extend for some distance on either side of it. This motor tract has been subdivided into three zones, one above the other, and each is connected with different portions of the body, as follows: the lower zone has to do with the movements of the tongue and lips, being that which is also concerned with speech; the middle one with movements of the hand and forearm; and the upper zone with those of both the arm and leg. The

anterior portion of the latter is connected with the arm as well as the leg, while the posterior part is concerned with the leg alone.

If we expose the brain of a monkey, for instance, and apply a slight faradaic current to this portion of the cortex, a localized epilepsy will result, and by such irritation of these various zones we are able to produce certain definite and special movements of different parts at will. These are the reasons, therefore, why we can arrive at a physiological basis for the location of the lesion in a case of this kind.

Let us next inquire, What empirical basis have we? Undoubtedly this is also sufficiently strong. In many instances of hemiplegic epilepsy tumors and other lesions have been found after death in this general district, and in the particular horizontal zone or zones corresponding with the parts that were noticed to be affected during life. The lesion may be either in the meninges or the brain-substance, or in both. Some time since a boy was under my care on Blackwell's Island who often had as many as ten or twelve epileptiform seizures in an hour.

Finally death ensued, this event being preceded, however, by well marked hemiplegia. At the autopsy it was found that there had been originally a fracture of the skull. On the inside of the cranium, at the point where this occurred, the dura mater was very firmly adherent to the bone, and attached to this was an enormous tumor. This proved to be of a sarcomatous nature, and it was as large as the fist, occupying almost entirely one of the hemispheres, and crowding to some little extent upon the other. When the tumor began to grow localized epilepsy was, no doubt, caused by the irritation thus set up in the motor zone. Afterwards, as it continued to increase in size, convulsions resulted, and at length there was the evidence of extreme pressure exhibited in the hemiplegia.

In our present patient, also, I believe that there is some lesion in the motor tract of the cortex, either in the upper or middle zone, or perhaps in both. The fact that there is no aphasia, imperfect articulation, or difficulty with any of the movements of the lips indicates undoubtedly that the lowest of the three zones is not affected. As to the exact nature of the lesion here, it is easier to say what it is not than what it really is. Thus, we can exclude syphilitic disease of the brain, because the man presents no evidence of having had constitutional syphilis, because there is no history whatever of such trouble, and, finally and most conclusively, because the test of treatment has already been applied, and a course of anti-syphilitics was followed by no benefit whatever. Again, there is little or no evidence of cerebral or other hemorrhage, although it is possible that he may originally have had an effusion of blood. We do not know exactly what the illness was from which he dates his trouble, but it is at all events a fact that after it his left side was left weak. This is a somewhat suspicious circumstance, and the amount of fever of which he has spoken in connection with it is quite compatible with the occurrence of cerebral hemorrhage. As to softening of the brain, that is hardly likely in this case. He has not had the degeneration of the arteries and other signs which ordinarily precede this condition, and he does not now present any of the symptoms characteristic of it, while both his age and his general appearance are entirely opposed to such a supposition.

What seems the most probable lesion here is a small tumor of some kind, which is causing pressure upon some portion of the two upper zones of the motor tract of the cortex. There are three varieties of diagnosis which I find it convenient to bear in mind in my practice, namely, the diagnosis of reasonable certainty, the diagnosis of probability, and the diagnosis of possibility; and I am sorry to say that I feel obliged to classify the hypothesis of the presence of a tumor in this case as a diagnosis of the third kind. The absence of headache here may be due to the fact that the tumor (provided there is one present) is a parenchymatous one, and does not involve the dura mater. When the latter is thus implicated, the patient usually suffers intense pain. The absence of lesion of the optic nerves is not significant. Even in the little patient previously mentioned, in whose brain there was such an enormous tumor, there was no neuro-retinitis. This is, however, more common when the tumor is situated at the base of the brain.

The prognosis is not very hopeful here; but still by means of an appropriate course of treatment I think we shall at least be able to ward off the epileptiform attacks. I have ordered for him the following prescription: ¹—

Ry Ammonii bromid.	ss.
Potassii bromid.	ss.
Aque	f 3 vii. M.

I always prefer to give the bromides with simple water, and not in the form of an elixir or mixed with syrups. A teaspoonful of the above solution (estimating seven teaspoonfuls to the ounce) will contain ten grains of the bromide of potassium and five grains of the bromide of ammonium, and he is at present taking two and a half teaspoonfuls of it (representing about thirty-eight grains) in the morning, and two teaspoonfuls (thirty grains) at night. This is only a beginning, and I shall probably be obliged to gradually increase the amount of the bromides taken. I desire, however, to find the *minimum* dose of these which will control the epileptic seizures, and it is a fact that this is often reached at a point considerably short of the amount required to produce bromism.

I shall also advise that the patient continue to wear the bracelet of which I spoke to you. For more than a thousand years the idea has prevailed that epileptic attacks may be controlled to a considerable extent by sudden pressure upon the wrist, and this was formerly practiced under the theory that the attack commenced in the hand. This is, of course, absurd. It is in the brain that the fit originates, and thirty years ago Brown-Séquard claimed that the bracelets, ligatures, and circular blisters which had so long been used in epilepsy acted by causing an irritation to be conveyed to the brain, and thus stopping the sensory manifestation. This was the principle of inhibitory arrest, which has since been studied more fully, and is now well understood. The patient will also continue to use the nitrite of amyl whenever he may feel the premonitions of an attack coming on; and this, it is well to know, acts more efficiently than any ligature can.

—Dr. Workman, of Toronto, has been elected president of the Ontario Medical Association.

¹ Expressed in the metric notation this would be: fifteen grammes of bromide of ammonium, thirty grammes of bromide of potassium, and two hundred grammes of water.

DESQUAMATIVE INFLAMMATION OF THE EAR.²

BY J. ORNE GREEN, M. D.

CASE I. Mrs. X., aged seventy-five, in good health, had been troubled for over a year with extreme deafness of the left ear, accompanied by a sensation of fullness; there had been some dull pain occasionally in the ear, but no discharge. Examination showed the meatus completely obstructed by a dark-brown mass, which was mistaken for inspissated cerumen, and she was ordered a solution of bicarbonate of soda in glycerine and water to soften it, and the next day I visited her to remove the offending body. The acoustical deafness was complete, that is, there was no hearing by means of the conducting mechanism; the bone conduction showed the labyrinth in good condition, and the tuning fork on the forehead was heard entirely in the affected ear. On syringing the ear a minute quantity of cerumen was removed, but the mass was not at all displaced. On examining with the probe I displaced a few fragments of epithelium from the mass and removed them with forceps. Recognizing now the nature of the obstruction, I gradually loosened masses and removed them, till finally, by inserting the probe along the walls of the meatus in different places, I was able to start the outer layers from the walls, and finally succeeded in getting a firm hold upon the outer edges with the forceps, and with some force withdrew the remainder of the mass. The operation required more than an hour before I finally succeeded in loosening and removing the outer layers.

After the removal the meatus was seen to be quite red throughout, and in spots were a few granulations. The membrana tympani was very much thickened in its dermoid layer, very much drawn in, and perfectly immovable. The acoustical hearing was improved to a fair degree by the removal, but was and remained imperfect, owing to the permanent changes in the membrana tympani and the rigidity of the ossicles. Examination of the removed mass showed it to be composed of laminae of large pavement epidermal cells, with some fat and an occasional crystal of cholesterine; its outer layer was of the same microscopic character, but was in one solid layer, like the finger of a glove, and showed an accurate cast of the meatus and drum-membrane, even to all the angles, prominences, and depressions of the latter. The small granulations of the meatus were canterized with solid nitrate of silver, once, shrivelled up, and caused no further trouble; the redness of the meatus disappeared rapidly. The age of the patient, and the great thickening of the drum-membrane, led me to advise no further treatment for the remaining deafness. I have never seen the patient since, and am unable to say whether there was any return of the mass in the meatus.

CASE II. John, aged eighteen, was sent me with a chronic otorrhœa of several years' standing, which examination showed was due to a purulent inflammation of the tympanum, and the drum-membrane was perforated in its upper posterior quadrant by an opening about three millimetres in diameter. A small projection of loose epithelium on the upper wall of the meatus, close to the membrana tympani, called my

² Read before the Society for Medical Observation, March 14, 1881.

attention to the spot, and with a bent probe I found that the upper and posterior wall of the meatus was largely destroyed; on removing the projecting epithelium another immediately came into view, and working with a bent probe mass after mass was removed, till finally, close to the bone, I succeeded in separating the innermost layers, and withdrew a mass of epithelial laminae, leaving a cavity into the mastoid antrum fully as large as the end of the little finger. The mucous membrane of the tympanum and antrum were red and swollen and secreting muco-purulent matter. Microscopic examination of the mass showed large pavement-epithelial cells, with and without nuclei, pus, fat, detritus, and some cholesterine. Instillations of sulphate of zinc were used, and several times the cavity required to be freed from epidermal flakes which had formed there. The otorrhœa finally ceased, the mucous membrane became pale and free from swelling, the formation of the epidermal flakes ceased, and the patient, as well as could be expected from the great destruction which had occurred, passed from observation, and has never been seen since.

CASE III. X., aged twenty-five, never had had any trouble with the ears till he began to be uncomfortable in the right ear (he could define it in no other way); there was no discharge, no pain, and no deafness. Examination at the City Hospital showed a dark-colored mass filling the lower half only of the meatus, and situated at about the junction of the osseous and cartilaginous passages. Examination with the probe showed it to be of the same character as the preceding deposits, and it was removed in the same way, by loosening the deeper layers from the walls of the meatus with a probe, and then removing it by forceps. The mass measured fully a centimetre in diameter, and was rather more than one centimetre long; it was torn apart, and consisted evidently of laminae of epithelium; was wholly destitute of any enveloping membrane; it was not examined microscopically. The seat of the mass was a large depression in the cartilaginous and osseous meatus, forming a cavity as large as the end of the little finger, and distinctly marked; the depression was probably due to an atrophy from pressure of the mass. The walls of the cavity were wholly free from congestion, and there was no solution of continuity in the epithelium lining it, which appeared perfectly normal. The membrana tympani was perfectly normal in appearance, and the hearing was normal. A few days after I saw the case again; there had been no further development of epithelium, and the ear was reported as free from its previous uncomfortable sensations.

CASE IV. Walter, aged eleven, after bathing in the salt water had a moderately severe earache in one ear for a few hours at night; no discharges followed, the hearing was not affected, and no more was thought of it till some weeks after, when his mother noticed an offensive odor, which was traced to this ear. On examining him I found a slight amount of pus on the upper wall of the osseous meatus, nearly one centimetre from the external drum-membrane. Wiping this away a small granulation was found to have developed from within the cancellated structure of the bone at this point, and there was a small curious cavity in the bone about one half a centimetre in diameter and the same in depth. It did not communicate with the tympanum, and that cavity was free from disease, and the hearing good. The granulation was removed,

the cavity was kept cleansed, was canterized occasionally, and it finally became covered with a cicatricial formation extending from the skin of the meatus over the walls of the cavity, and the cure was complete, although the cavity still remained open into the meatus. The ear remained well for a year, when a slight odor was again noticed, and examination showed a little discharge, and the cavity filled with epidermal flakes, which were removed as in the other cases. Cleansing and astringents were used, and the discharge soon ceased, but there was a marked tendency to reproduction of the flakes for some weeks, requiring their occasional removal with the bent probe. This tendency finally ceased, and the ear remained well more than a year afterwards, the cavity remaining, but lined with firm cicatricial tissue.

CASE V. Mrs. X., aged forty, had suffered from chronic purulent inflammation, with perforations of the drum-membrane, years ago, and under the care of the late Dr. E. H. Clarke had recovered at least so far that the discharge had ceased, and she was not aware of any trouble remaining. Five years after this there was a return of otorrhœa, which was again relieved, and the ear had remained free from discharge for ten years, when from debility while nursing, as she thought, the otorrhœa began again, and after several weeks' duration I was consulted. I found with the otorrhœa quite large granulations filling the meatus and occluding the view of the deeper parts. Under ether these were readily removed by a wire *érasaur*, and proved to be papillomata from the walls of the meatus. Behind these growths the whole osseous meatus was filled with epithelial masses, which were only loosened and removed with great patience and difficulty, the time occupied being nearly an hour. After cleaning the meatus the membrana tympani was found perforated, and through the perforation projected a small polypus originating from the tympanic mucous membrane, which was also removed with the *érasaur*. The case was treated by cauterization, cleansing, and inflation till all discharge ceased, some months afterwards. There was but a slight tendency to reproduction of the epithelial masses, which soon ceased. The case remained well several years afterwards.

These cases, with the exception of the third, the only one of the kind I have ever seen, might be multiplied, but they are sufficient to call attention to the different varieties of conditions under which large masses of epidermis are thrown off and form important collections in the ear requiring instrumental interference. It will be noticed that they are of three kinds,—collections in the meatus without any affection of the deeper parts, collections in the meatus associated with purulent inflammation of the tympanum, with perforation of the drum-membrane, and collections in the cavities of the middle ear associated with purulent inflammation of the tympanum. The character of the collections was the same apparently in all; microscopically, when they were examined, they consisted of layers of large pavement epithelium cells, with and without nuclei, fat globules, crystals of cholesterine in variable quantity, and detritus. In all of the cases which I have given, except the third, they were associated with inflammation of the surfaces to which they were attached,—meatus, mucous membrane of the tympanum. The third case is the only one of the kind I have ever seen where there was such a collection involving and only attached to a portion of the meatus;

in that case a very distinct depression existed in the bony wall, which I referred to an atrophy from the pressure of the mass.

From the constituents of these collections and their association with inflammation it would readily occur to any one that we were dealing with a retention of the products of inflammation; but the collections once formed, they become the prominent and difficult feature in the case, and the histories of similar collections afford some curious facts, which are well worthy of further study by the microscopist and pathologist. Such histories show apparently that the collections are not always associated with distinct and well-recognized inflammation; that collections of similar constituents have been classed as new growths; that similar collections sometimes occur within the tissues instead of upon their surfaces.

Cholesteatoma of the temporal bone was formerly considered to be always an independent and primary new growth, and Troeltsch was the first to assert that, at least, many of these so-called tumors were in reality merely collections of inflammatory products consisting of collections of concentric layers of epidermis cells and occasional cholesterol crystals around a nucleus of fat and caseous pus. Wendt, some years since, made a careful study of a number of these cases of so-called cholesteatoma and similarly constituted collections, which were published in the *Archiv für Heilkunde*, vol. xiv. His conclusions were, in brief, as follows:—

(1.) In the external meatus and in the osseous middle ear there are sometimes found collections of a peculiar, usually cerumen-like, mass.

(2.) These are due to a *desquamative inflammation*, by which scales of epidermis are formed and thrown off from the mucous membrane of the osseous middle ear, the epithelium of which, during or after an inflammatory process, may assume the character of the skin and a rete Malpighii be formed.

(3.) Such masses may produce deafness by obstruction, and pain by pressure.

(4.) They may produce important changes in parts of the ear, in the petrous bone, and even in the contents of the skull by their pressure, and other troubles, perhaps, by absorption of their constituents in a state of decomposition.

(5.) Their removal is all-important.

(6.) It is not improbable that similar masses formed in the meatus as the result of a chronic inflammation may get into the middle ear when the drum-membrane is perforated, and produce similar collections in that cavity.

(7.) The cholesteatomata described as composed of collections of epidermis cells are also to be regarded as the products of a desquamative inflammation in the middle or external ear unless a thorough examination, which must be more than a simple investigation of the collection itself, proves another origin.

This paper of Wendt's is the first application of the term desquamative inflammation to the formation of these masses, and it is so descriptive of the condition that is found in many cases, that it seems to me worthy of more general adoption than it has received, as not infrequently the collection is the prominent feature in the case. Buck, in his recent work on the ear, adopts the term, and describes desquamative inflammation both of the meatus and tympanum; he also calls attention to the obstinacy of the affection, and to the very great tendency to fresh collections.

It is, however, possible that Wendt's description is not applicable to all cases of cholesteatoma: as Troeltsch has said in a criticism of Wendt's paper, it is very probable that in the cholesteatoma of the petrous bone of authors various formations have been included. Schwartz asserts that in some of the least common cases cholesteatoma, called by Virchow pearl tumor, and by Toynbee molluscons or sebaceous tumor, "is a true new growth arising from the bone, from the skin of the meatus, from the membrane tympani, or the mucous membrane of the tympanum, analogous to the cholesteatoma of other bones of the skull, the brain, or the meninges. It consists in such cases of a thin fibrous capsule which contains a substance resembling stearine, and glistening like mother of pearl, the morphological elements of which are chiefly flat cells of polygonal shape (epidermal cells), and also often, but not constantly, crystals of cholesterol in small numbers." Lucae has also found in them nucleated giant cells. In the earlier stages of these true new growths all inflammatory irritation is said to be wanting, although later there may be suppuration and a destructive tendency. The fibrous enveloping capsule seems to be their distinguishing character with absence of fat and caseous pus. The presence of giant cells does not seem to be important, as similar flat polygonal cells three or more times larger than the normal pavement epithelium of the tympanic mucous membrane are found also in the false cholesteatoma, desquamative inflammation, and Troeltsch has sometimes found these gigantic flat cells in the covering of the antrum mastoideum, usually with collections of pus in this cavity. Schwartz agrees with Wendt and explains the presence of giant cells from the fact that under a chronic purulent inflammation with defect of the drum-membrane the tympanic epithelium often assumes the characteristics of the skin, showing a rete Malpighii and epidermis.

A collection of nearly similar composition with these which we have been considering is described by Wendt in the *Archiv für Heilkunde*, vol. xv., as occurring in the membrana tympani. From his microscopic studies of the substantia propria of the drum-membrane he found it to consist of coarse and fine bundles of fibrous tissue surrounded by delicate hyaline capsules, very resistant, and covered with cells of various forms, round, oval, or star-shaped, which he considered were endothelial. Between the bundles of fibres were communicating spaces, the whole arrangement forming lymph-canals lined with endothelium. In the right membrana tympani of a man who died from typhus he found a true endothelial cholesteatoma developed from the endothelium of these lymph-canals. The macroscopic examination of the drum-membrane showed upon its inner surface a projecting hemispherical mass one and a half millimeters in diameter of a translucent gold color. The tympanic mucous membrane was swollen and hyperæmic; the membrana tympani with several small perforations thickened, and its epidermis of a dirty gray color. The tumor itself was surrounded by a connective-tissue capsule which contained hamatoidin, and was lined by a cylindrical or cubic epithelium. The substantia propria showed several cavities filled with parallel and concentrically arranged membranes, which had pressed aside the fibrous bundles; these membranes contained numerous nuclei, and among them were crystals of cholesterol and fine drops of fat, showing a retrogressive metamorphosis.

Urbantschitsch in the *Archiv für Ohrenheilkunde*,

vol. x., and Politzer in his *Lehrbuch der Ohrenheilkunde* have described similar growths in the epidermal layer of the drum-membrane under the title of epithelial growths. They occur singly or in numbers upon the external surface of the membrane, and Politzer says: develop usually during the course of chronic inflammation of the middle ear, as small round knobs which disappear spontaneously. He figures a case in which eight of these growths are distributed over a semi-circle upon the outer surface of the membrane. Politzer found in one case which he was able to examine epithelial cells, cholesterine, and molecular detritus. In all of the cases of these growths which have been described, the ear was or had been recently in a state of inflammation; no account is given by Politzer of any investing capsule in the case examined by him. The case of Wendt's, which was subjected to a most rigid microscopic examination showing it to be a true new growth, was also associated with tympanic inflammation.

Lucæ in the *Archiv für Ohrenheilkunde*, vol. vii., is very decided in his opinion that pearl-tumor, as he prefers to call it, to avoid the name cholesteatoma which might be confounded with cysts containing cholesterine, is a true heterologous growth, and quotes a case where such a tumor was found in the mastoid antrum with an intact drum-membrane, and the mucous membrane, from which, or on which, it arose, was absolutely free from every trace of inflammation or granulation. In all the other cases which he gives however, amounting to ten, there was, or had been, a chronic inflammation of long standing in the middle ear.

From what has been said it is evident that we may have large collections, composed chiefly of epidermis, of three kinds: (1) desquamative inflammation of the meatus, membrana tympani or tympanic mucous membrane; (2) pearl-tumor of the tympanic mucous membrane; (3) endothelial tumor of the lymph-spaces in the drum-membrane.

The characteristics of the pearl-tumor seem to be the enveloping capsule and the presence of heterologous tissue cells differing from those of the parent soil in being three or more times larger. In regard to the first point, the enveloping capsule, it is by no means clearly made out in a large number of the cases which have been described as true new growths; in regard to the large cells, the so-called giant cells, they are accurately described by several authors in both the true and the false cholesteatomata so that it does not seem proper to lay too much stress upon them. Of late years the evidence seems to be accumulating in favor of the inflammatory and retention theory even of the pearl-tumors.

It is, however, certain that the cavities of the external and middle ear are particularly pre-disposed to large epidermal collections, which produce symptoms in themselves, and which also by their growth may cause atrophy, caries, and inflammation of contiguous parts, and as the process by which these collections are formed is a peculiar one a distinctive name for it is desirable, and such is found in the term desquamative inflammation given by Wendt.

— It is proposed to fill one of the vacant nights of the approaching International Congress by a *fête* at the Botanical Gardens. The corporation of London will entertain the Congress at a *soirée* in the Guildhall at a cost of two thousand pounds.

THE CHARACTERISTIC APPEARANCE OF WOUNDS OF THE INTESTINES MADE DURING LIFE.

BY W. F. WHITNEY, M. D.,

Curator of the Warren Anatomical Museum.

THE difficulty, at times, with which wounds of the intestines are found while the organs are *in situ*, and the frequency with which the intestines are wounded during their removal from the body even by the most skillful examiner, renders a knowledge of the appearances presented by wounds made before death of great value to the pathologist.

The relation which the mucous coat bears to the edges of the wound is characteristic, and when carefully considered will leave little doubt as to the time when the wound was inflicted. The older writers have well described the appearance of ante-mortem wounds of the intestines, but have not sufficiently dwelt upon the importance of this relation as a diagnostic mark, while the more modern text-books seem to have passed it over entirely.

The characteristic feature of ante-mortem wounds is that the edges are covered by a protrusion of the mucous coat. A consideration of the arrangement and action of the coats of the intestine will shew why this would be expected, and a simple experiment will demonstrate it. The mucous coat is loosely connected to the muscular coats, and movable upon them to a certain extent. If all the coats of the intestine are divided the edges of the wound will gape from the retraction of the cut muscles, and the lax mucous coat is forced through the opening by the peristaltic movement as far as its attachments will permit, and curls back over the edges of the wound through the action of its elastic fibres.

This extrusion of the mucous coat can be readily seen if the abdomen of an animal is opened before the peristaltic motion has ceased, and a small cut be made into the intestine. Once over the edges of the wound the membrane is not retracted again, and if the experiment has been performed upon a living animal it becomes adherent in its new position from the inflammatory action which is set up. A few hours are sufficient for this to take place. In the case of one rabbit operated upon, only twelve hours elapsed before its death, and the adhesion was found to be quite firm.

Besides this position of the mucous coat there is a slight thickening of all the coats immediately in the neighborhood of the wound from an infiltration with serum and new cells. This was well shown in sections prepared from the edges of the wound from a rabbit that was killed thirty-six hours after operation.

Two cases in which there was a possibility that the lesions found at the autopsy might have been produced in other ways than by violence before death first called my attention to the subject.

CASE I. A man forty-five years old was admitted to the Massachusetts General Hospital thirty-six hours after having fallen the distance of two feet from a plank on which he was sitting, striking upon his buttocks, with the symptoms of great abdominal pain and constant vomiting, which he stated commenced soon after the accident. He had a double inguinal hernia which always reduced itself upon lying down, but now the one on the left side could not be entirely replaced. The day after entrance the possibility of an internal strangulation was regarded, as the symptoms had not abated,

and it was decided to operate. The patient was etherized, and the sac opened, when the bowel was found to be greatly inflamed and roughened, but could be easily replaced. The patient did not rally and died within an hour. At the autopsy there was found a general peritonitis, no appearances of strangulation and a small opening into the intestine.

It was thought that the wound might have been made at the time of the operation; but the edges of the wound being covered by the mucous coat, which is firmly adherent over them, leaves no doubt that the wound had occurred, not only during life, but also many hours before death and was a rupture caused by the fall sixty hours previous.

CASE II. The specimens were presented to the Warren Museum by Dr. F. A. Harris, Medical Examiner, who has kindly allowed me to use the case. A woman was brutally kicked about the groin and abdomen by her husband. Symptoms of peritonitis developed, and she was removed to the Massachusetts General Hospital, where she died thirty-six hours after the injury. The autopsy showed extensive ecchymosis over the upper part of the right thigh, but none of the abdominal walls. Upon opening the abdomen a general peritonitis with a dirty purulent effusion was seen. There was laceration of the omentum, and a small opening into the intestine, about four feet above the ileo-cæcal valve, was discovered while the organs were *in situ*. Upon their removal from the body another opening higher up was found and which I thought I had accidentally made in opening them. Careful examination of the edges showed that both wounds were alike and both presented the characteristic appearances of wounds occurring some hours before death, namely, the edges covered with the mucous coat firmly adherent to them and to the peritoneal surface for a short distance beyond, showing that two ruptures of the intestine were produced by the violence to which she was subjected and caused her death.

In conclusion it is to be stated that there is no difference in the appearance of wounds following rupture from violence as in the two last cases, and in wounds produced by cutting as in the case of the rabbits operated upon.

RECENT PROGRESS IN THE TREATMENT OF CHILDREN'S DISEASES.

BY D. H. HAYDEN, M. D.

SEVENTEENTH ANNUAL REPORT BY PROFESSOR DEMME OF THE WORK DONE IN THE JENNER CHILDREN'S HOSPITAL IN BERNE DURING THE YEAR 1879.¹

FOLLOWING the statistical summary of children treated in the hospital and in the out-patient department, there is given an account, as in other years, of the author's experiments with various artificial foods for infants, as a result of which the infant's food of the "Cham Society" and that prepared by Tambur are added to the list of older preparations suitable for infants six to eight months old. Biedert's "cream mixture" proved itself useful repeatedly in obstinate cases. The counting of the blood corpuscles, with the different methods of feeding, showed an excess of the white corpuscles in children which were fed too early with starchy food, and often an easily-demonstrable

¹ Centralblatt für die medicinischen Wissenschaften, December 18, 1880.

improvement in the quality of the blood (increase of the red corpuscles) eight to ten days after changing the food, especially after placing the child to the breast. In one case there ensued a marked improvement after the transfusion of human blood with Pravay's subcutaneous syringe, two syringe-fuls being injected with an interval of three days between them. The blood was drawn into the syringe, previously warmed, from a vein, and in like manner injected. The author calls attention to the great importance of having good cows' milk, and enumerates many diseases possible to arise from the use of diseased cows (tubercular), or badly-fed cows, particularly the repeatedly-observed stomatitis aphthosa caused by the use of milk of cows fed improperly.

In a description of the relations existing between "the diphtheritis of scarlet fever" and "the pure primary diphtheritis (cynanche)" Professor Demme expresses himself in agreement with those who see therein the different diseases which can, however, in rare cases complicate each other. These latter cases he would designate as "diphtheritis of scarlet fever" as being cases of genuine diphtheria, the others, being peculiar to scarlatina alone, he would call "the catarrhal scarlatinal inflammation of the tonsils and pharynx," and "scarlatinal necrosis of the pharynx." Of unique cases particular mention is made of (1) a congenital tumor, tubercular in character, the size of a hazel nut, situated in the middle of the right hemisphere of the cerebellum, which was found in the case of an infant, female, twenty-three days old, which had been the cause of no symptoms. (2.) Case of recovery from epilepsy in a boy seven years old, of two years' duration, after the removal of a rectal polypus. (3.) Medullary carcinoma of the thyroid gland and of the left mamma in a boy five years old, the first having made its appearance in the third year, the latter in the fourth year of life. (4.) Pulsating struma in a girl seven years old, which began suddenly to grow after scarlatina, and which rapidly diminished in size, and ceased to pulsate, after the daily subcutaneous injection of one milligramme (grain $\frac{1}{100}$) of nitrate of strychnia. The residue was still further reduced in size by the injection of two to three drops of tincture of iodine into the tumor itself. In conclusion, the author gives a short summary of seven hundred and ninety-three cases of struma which came under treatment in the hospital between 1862 and 1879, of which 317 were boys and 476 girls. (5.) A congenital stricture of the œsophagus, in a girl five years old, with marked improvement through the continued use of bougies.

CHRONIC TUBERCULAR PERITONITIS.²

Professor Henoeh, at a meeting of the Berlin Medical Society, held November 24, 1880, at the conclusion of the report of a case where the disease began with pericarditis with a large effusion, was followed by ascites, and later by tubercular meningitis, and where the autopsy showed general tuberculosis, made some interesting remarks upon the subject of chronic tubercular peritonitis. He called attention to the quite frequent absence of any pain in the abdomen in this disease, and to the error of supposing that there must be tenderness on pressure in such cases. Cases undoubtedly happen where children complain of pain when strong pressure is made; but Professor Henoeh has seen many more cases where there was absolutely no

² Berliner klinische Wochenschrift, January 10, 1881.

complaint, and where the only symptom present was a progressive enlargement of the abdomen, with, finally, a protrusion of the umbilicus and dilatation of the abdominal veins. At the same time there was a continuously increasing emaciation. In the case reported, an interesting fact, observed for the first time by Professor Henoeh, was a leakage of the ascitic fluid through the umbilicus, trickling as from a sieve, and thus in part relieving the distended abdomen from a part of its contents. The discharge of peritoneal abscesses is not so uncommon through or alongside the navel, but the discharge of ascitic fluid in this way is something he had never seen before.

The author concludes with a consideration of the question whether there is such a thing as a chronic peritonitis without tuberculosis in children. He believes that there is, and reports such a case where the autopsy showed a simple chronic peritonitis, with enormous callous formations and connective-tissue growths. Other cases have been met with where there was so great resemblance to tubercular peritonitis that at first the differential diagnosis was impossible, and only at the end was this made by the fact of recovery. The children have an enlarged abdomen, which becomes more and more distended from month to month; there is no complaint of any pain, or at least it is very transitory; the abdominal veins become dilated; palpation and percussion detect a fluid, whilst examination of the lungs shows nothing abnormal. This latter is no proof against tuberculosis, for it has been shown by Rilliet and Barthelz that tuberculosis of the peritoneum and abdominal organs can exist without extending to the lungs. When, therefore, the lungs are free this does not show that the peritonitis is a non-tubercular one. In these cases there is much to make one think of tuberculosis, especially as the children become more and more emaciated and wretched. Professor Henoeh remembers five or six cases which recovered, one in particular, where the abdomen became so distended, and where the child became so wasted with hectic fever, that a fatal prognosis was pronounced, and yet recovery took place. Such cases Professor Henoeh would not speak of as tubercular peritonitis. It is possible that tubercles in the peritoneum may heal; but he would prefer to assume that in children who are not tuberculous and who come from perfectly healthy stock, a simple chronic peritonitis can take place, the cause of which is often not ascertainable.

The treatment in the author's cases consisted of long-continued (weeks, months) hydropathic wrappings of the abdomen. The abdomen was also painted with tincture of iodine, one fourth at a time. With regard to the alleged danger, in employing iodine with children, of producing albuminuria, the author has only to say that this never happened in his cases, and it cannot therefore be a so common accident as the French would make it out to be. Internally nothing was given but decoction of cinchona, alone or with acetate of potash; later iron. Bran baths were also employed. Thus the disease was left principally to the curative powers of nature, and the treatment had little to do with the recoveries.

PILOCARPINE IN SCARLET FEVER AND DIPHTHERIA.

The author's first contribution on this subject appeared in the *Revue Médicale de la France* (Paris), in the *Children's Hospital Bulletin*, No. 1, 1877, p. 1. It was also published in the *Revue Médicale*, xxv, Boud, H. H. 3 and 4, March 31, 1878.

appeared in 1877, when the remedy had been used by himself in thirty-three cases.²

The present very instructive and interesting article may be looked upon as a further contribution in the same direction, the author's experience having been enlarged by forty-two new observations. The conclusions arrived at are summed up at the end as follows:—

(1.) The different statements as to the efficacy of muriate of pilocarpine is in part explainable by the not yet separated presence in greater or less quantity of a second alkaloid of the jaborandi leaves, "jaborin." The physiological action of the latter, according to Harnak and Meyer, resembles that of atropia. The action of the former is more like that of nicotine.

(2.) The initial dose for subcutaneous injection should be from the end of the first year to the end of the tenth year 0.005 grammes (one twelfth grain), before the end of the first year 0.001 to 0.0025 grammes (one sixtieth to one twenty-fourth grain). When found to be well borne the dose can be used of double size, and several times daily. When administered internally the dose must be twice or three times larger, dissolved in distilled water, fifty to seventy-five grammes (about two ounces) with the addition of gum acacia if there is a disposition to diarrhoea.

(3.) Where the indications for a rapid effect are urgent (in uræmia, croup, etc.) the subcutaneous injection is much to be preferred, where a continuous and lasting effect is wanted the continuous and divided dose through the day is more appropriate.

(4.) Vomiting or symptoms of collapse that sometimes follows the subcutaneous injection of pilocarpine can, as a rule, be prevented by a previous administration of cognac, wine, strong coffee, or tea, likewise by a subcutaneous injection of ether. The same employment of stimulants is recommendable when the medicine is given internally.

(5.) By moderate doses, and when employed only for a short time, no weakening effect upon the heart will be noticed. When larger doses are given several times daily, over 0.01 (one sixth grain), and when the treatment is continued for two or three weeks, there ensues a diminution of the energy of the heart's contractions, manifested by irregular fluttering pulsations, with a sinking of the temperature, and the symptoms of a general collapse. As a result of the weakness of the heart there can ensue a transitory loss of consciousness and the Cheyne-Stokes respiration. With a cessation of the pilocarpine and the administration of stimulants these symptoms are rapidly removed.

(6.) The susceptibility to the action of pilocarpine varies very much in different individuals, also in the same individual at different times. There sometimes exists a vicarious relation between its diaphoretic and sialogogue action. As a part symptom of the general stimulation to the secretions, a marked expectorant effect is observable, especially, in certain cases, an abundant secretion of the nasal, laryngeal, and tracheal mucous membrane.

(7.) Another effect, though not constant, which takes place either at the height or at the end of its diaphoretic action, is an increase in the secretion of urine. The cause of the diuresis is to be found in the increased blood pressure caused by the pilocarpine, and the rapidity of the blood current in the vessels of the glomeruli, and perhaps also in the action of the

² Vide this JOURNAL, January 17, 1878.

medicine upon the innervation of the vessels of the kidneys, or even upon the central nervous system (floor of the fourth ventricle).

(8.) The erythema extending over the greater part of the body, which is occasionally observed at the beginning of the sweating, is due to the irritation, produced by the pilocarpine, of the peripheral system of vessels, especially of the capillary net-work of the skin.

(9.) In those cases of scarlatina where there is a delay in the appearance of the eruption, or where it is incomplete, and at the same time where there take place dangerous cerebral symptoms, as sopor, convulsions, etc., an energetic diaphoresis effected by pilocarpine, by subcutaneous injection, will remove in the quickest way from the blood the scarlatinal poison circulating therein, will bring out the eruption more completely, generally in an intense degree, and in this way most effectually put a stop to the cerebral symptoms.

(10.) Pilocarpine has no power to ward off or prevent the appearance of nephritis whether in an earlier or later stage of the disease by its employment regularly from the beginning or during the stadium floridum. On the other hand, it is an effectual remedy against dropsy as a symptom. The course of the kidney affection appears also to be a more favorable one under its use.

(11.) An attack of uræmia, in the course of a scarlatinal nephritis, in the rapidly developing forms of an extensive glomerulo and interstitial inflammation, cannot be prevented by the employment of pilocarpine. In cases of less severity and running a slower course a timely and continuous diaphoretic and diuretic action of pilocarpine is competent to ward off attacks of uræmia threatening to life, and likewise to cure them quicker than any other remedy hitherto employed.

(12.) As a part symptom of the general stimulation of the secretions is to be noted the expectorant action of pilocarpine by increasing the secretions of the mucous membrane of the respiratory tract, and a thereby liquefying of tough sputa. This effect contributes towards a more rapid recovery from catarrhal laryngitis, from genuine non-infectious and infectious croup, from catarrhal pneumonia, etc., also by its emetic action—like any other powerful emetic, though more lasting,—to the removal of symptoms of laryngo and tracheo-stenosis immediately threatening life. In genuine diphtheria, and in the so-called diphtheritic disease in scarlet fever, we observe, as an analogous effect, a more rapid and spontaneous loosening of the diphtheritic membrane and of fibrinous infiltrations of the mucous membrane. No specific action upon the infectious matter of the disease itself was demonstrable in the observations made by the author.

—The business of the London International Congress will be conducted in sixteen sections, and the arrangements of the general meetings include addresses to be delivered on Wednesday by Sir James Paget; on Thursday by Professor Huxley, who will take as his subject the connection of the biological sciences with medicine; on Friday, in German, by Professor Volkmann on modern surgery; on Monday, by Professor Raynaud, in French, on skepticism in medicine in past and present times; on Tuesday, by Surgeon Billings, on medical literature.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. JOHN G. BLAKE.

REPORTED BY DR. JOHNSON, HOUSE OFFICER.

I. INTESTINAL OBSTRUCTION.

P. D., aged thirty-eight, entered the hospital December 22, 1880, with the following history: Has had no defecation for four weeks. Constipation commenced the trouble, and the defections grew less in amount and after a few days there was no desire to have a movement from the bowels; knows of no cause; thinks his trouble is due to dyspepsia and constipation, the latter symptom having been present for several months; has had more or less pain in the abdomen for the past four weeks; nausea and vomiting for the past two weeks; no appetite; nasty taste in mouth, which feels dry; no thirst; tongue dry and slightly coated; has lost flesh and strength; no swelling of feet or legs; temperature 99° F.; pulse 90; respiration 36; he was given the following. *R.* Sulphate of morphia, one tenth grain; extract of belladonna, one third grain. *M.* Take in pill form every three hours. Abdomen to be covered with hot flaxseed poultice. Beef extract and broth by mouth.

P. M. Retention of urine. Catheter passed and 3xxi. of urine withdrawn.

December 23d. Increased pain in abdomen for past six hours; catheter passed, and 3xii. of urine withdrawn, and pain relieved; temperature 97° F.; pulse 82; patient's general condition fair.

December 24th. Abdomen distended and tympanitic; intestines aspirated and tympanitis relieved; pulse weaker; temperature normal. *R.* Brandy 3ss. every two hours.

December 25th. Patient very comfortable; little or no pain during the night; complains of sleeplessness; rectal tube passed into bowels and a large amount of warm suds injected without any apparent effect.

December 26th. Abdomen again tympanitic; tympany relieved by aspiration of bowels. *R.* Brandy, 3ss.; beef extract, 3ii. *M.* Taken by rectum every two hours; milk punch ad lib.; pulse 136; temperature 103.

December 27th. *R.* Quiniae sulph. gr. v. t. i. d. by rectum.

P. M. Temperature 101° F.; pulse 126; retains enemata fairly well.

December 28th. Patient stupid and slightly narcotized; omit ordered pill. *R.* Brandy, 3i. every hour.

December 29th. Delirium during the night; complains of pain in abdomen; resume the morphia and belladonna pill, one every three hours; temperature normal; pulse 105; rectal tube passed, and between five and six ounces of spirits of turpentine in two quarts of warm suds injected into the bowels. From this injection there resulted a very large defecation, which was hard in consistency and of a slaty color. At this time a great deal of gurgling was heard in the abdomen, though no gas escaped per anum.

Two hours after the above injection patient had a similar though smaller defecation. He is much ema-

ciated and failing fast; abdomen distended and superficial veins full; occasional retention of urine; the right parotid gland, which was slightly swollen yesterday, has increased to the size of the fist, and is hard and tender; patient has vomited but four times since entrance.

r. m. Ringing in ears; omit quinia.

December 30th. Patient slept well during the night; somewhat under the influence of opium; omit pill of morphia and belladonna; abdomen distended with air; distention relieved by aspiration; redness, swelling, and induration over nose and to an inch on either side; especially marked about the right eye.

Strained gruel to be added to ordered enema.

Six *p. m.* Temperature 102.8° F.; pulse 128; patient has failed a great deal during the past twenty-four hours; champagne and brandy, *p. r. n.*

December 31st. Temperature 100° F.; pulse 118; right eyelid so swollen that patient cannot open it; delirium during the night. *R.* Sulphate of morphia, one tenth grain; extract of belladonna, one tenth grain. *M.* Take every three hours in pill form. Patient's tongue has gradually become dry and brown.

Twelve *m.* Pulse scarcely perceptible. Has not retained enemas for past twelve hours; rapidly failing; died at 1.30 *p. m.*

II. CONSTIPATION.

E. R., aged twenty-two, entered the hospital January 20, 1881, with the following history: well until three months ago, then menstruation ceased; thinks she is pregnant; menstruation had always been regular up to that time; vomiting since menstruation ceased; most at night and very early in the morning; has had no defecation for twenty-nine days; complains now of headache, pain in eyes and breast; tongue slightly coated; no trouble with micturition; appetite good; has lost flesh and strength; temperature 98° F.; pulse 100; has always been constipated; on one occasion, previous to the present trouble, she went without a defecation for five weeks; complains of flatulence; the following was given per rectum: *R.* Ol. terebinth, $\text{℥}\text{iii}$.; ol. ricini, $\text{℥}\text{iss}$.; aqua, *℥j*. *M.* To be repeated three times at intervals of two hours.

R. Sulphate of magnesia one drachm in half a tumbler of water every hour for six hours, provided there is no defecation before the six doses have been taken. The first dose to be given two hours after the last enema.

January 22d. All the enemas were given, and after two doses of the sulphate of magnesia patient had a large defecation.

January 24th. Vomiting since early this morning; twenty grains of chloral were given per rectum and vomiting was relieved.

Nausea and vomiting commence every morning about five o'clock.

Patient ordered twenty grains of chloral per rectum every morning at 4.30 o'clock. Had no return of the nausea or vomiting while she remained in the hospital.

January 27th. Discharged well.

III. DIPHTHERIA.

The following line of treatment was carried out in the cases reported below:—

Steam impregnated with carbolic acid was allowed to enter the room freely.

Whisky was invariably given, the dose, and fre-

quency of repetition, depending on the age and the condition of the pulse.

The pharynx, tonsils, soft palate, and uvula were thoroughly painted four times a day with tincture of ferri chloridi.

The tincture of ferri chloridi was given internally four times a day.

Good generous diet was given, the bowels were kept open, and everything was done to make the patient as comfortable as possible.

CASE I. *M. T.*, aged eighteen, entered the hospital January 5th, with the following history: Difficult deglutition for two weeks; one week ago was obliged to give up work and go to bed on account of weakness; nausea and vomiting for past seven days; has slight cough; no trouble with micturition; bowels constipated.

January 5th. Diphtheritic membrane covers whole of left tonsil.

January 9th. Diphtheritic membrane now covers uvula.

From this date there was steady improvement. On the 15th inst. patient was allowed to sit up, and on the 17th inst. patient was discharged well.

On entering the temperature was 100.8° F.; the pulse 120. Both temperature and pulse reached the normal line four days after patient was admitted.

CASE II. *E. C.*, aged five, entered the hospital January 15th with the following history: Throat has been swollen and deglutition difficult for past three days; pain in back; feels weak; tongue coated; bowels regular; no trouble with micturition; temperature 102.2° F.; pulse 120; diphtheritic membrane covers both tonsils, and uvula.

January 19th. Membrane disappearing.

January 21st. Membrane entirely disappeared.

January 22d. Patient taken home against advice. The temperature reached the normal line on the third day after admission, and the pulse on the fourth day.

CASE III. *J. N.*, aged twenty-five, entered the hospital January 15th. Four days ago was taken sick with severe pain in abdomen, head, and back; two days since felt weak and first noticed difficulty in deglutition; tongue heavily coated; bowels regular; no trouble with micturition.

Glands at angles of lower jaw much swollen; tonsils very much enlarged and covered with a slough; diphtheritic membrane covers soft palate and uvula.

January 30th. Membrane has disappeared.

January 31st. While up thinks he "took cold"; intense injection of pharynx and tonsils.

Throat no longer painted with tincture of ferri chloridi, but nitrate of silver, thirty grains to the ounce of water, substituted.

February 5th. Discharged, well.

The temperature reached the normal line on the fifth day after admission; the pulse never rose above 90.

CASE IV. *S. R.* aged six, entered the hospital January 20th. Sick two days; feels weak; headache; neck somewhat swollen; deglutition painful; bowels constipated; no trouble with micturition; temperature 105° F.; pulse 155. Membrane covers right tonsil.

January 22d. Membrane has disappeared.

February 2d. Discharged well.

Temperature and pulse gradually fell from the day of entrance until they reached the normal line.

CASE V. *L. L.*, aged twenty-two, entered the hospital January 20th. Says she had diphtheria last June.

Present sickness began one day ago with headache, backache, pain in limbs. Neck somewhat swollen. Patient feels weak; bowels constipated; no trouble with micturition; tongue coated with brown fur; some nausea and vomiting.

January 21st. Nausea and vomiting this morning at 7.30. At eight o'clock A. M. chloral, twenty grains, given per rectum; no vomiting after nine o'clock A. M.; membrane covers right tonsil; pharynx considerably injected; tonsils enlarged and injected.

January 22d. Membrane has disappeared.

January 26th. Discharged, well.

The temperature never rose higher than 100° F., and on the fifth day it reached the normal line. The pulse, which was 90 on admission, gradually fell to the normal line.

CASE VI. L. R., aged twenty-four, entered the hospital January 20th. Sick one day. Sickness commenced with a chill, headache, pains in back, and difficult deglutition. Appetite good; bowels constipated; diphtheritic membrane covers both tonsils.

January 22d. Membrane has nearly disappeared.

January 27th. Membrane has entirely disappeared.

January 31st. Discharged, well.

On entrance the temperature was 103.8° F.; on the third day it had reached the normal. The pulse on entrance was 120; on the third day it had reached 80.

CASE VII. I. B., aged twenty-three, entered the hospital February 13th with the following history: Subject to sore throat. Present sickness commenced ten days ago with painful deglutition; five days later headache commenced; obliged to go to bed on account of weakness; since being in bed has had pains in joints; tongue heavily coated; bowels constipated; no trouble with micturition; appetite good; temperature 100° F.; pulse 88; tonsils much swollen, especially the right one; pharynx, uvula, and tonsils much injected; a somewhat disorganized membrane scattered in patches over right tonsil; a membrane the size of a thumb-nail on posterior wall of pharynx; a membrane the size of little finger-nail on left tonsil.

February 16th. Membrane has entirely disappeared. Patient discharged, well, at own request.

Temperature never rose above 98.4° F.

CASE VIII. C. D., aged three years and six months, entered the hospital February 17th. Glands of neck much swollen; patient very weak; tongue heavily coated and dry; temperature 102.5° F.; pulse 130; respiration 60; patient has been sick ten days; diphtheritic membrane covers nearly the whole pharynx, both tonsils, and uvula.

February 18th. A copious discharge from nose; respirations free, but fifty to the minute. Throat atomized every few hours with the following: \mathcal{R} Sodæ salicylatis two grains, tr. ferri chloridi \mathfrak{z} i., aquæ \mathfrak{z} ss. M.

February 19th. Pulse continues good; respirations less rapid than yesterday. \mathcal{R} Quinæ sulph. gr. ss. every three hours.

February 20th. Pulse rapid and weak; nostrils covered with dry mucus; passed a very restless night.

February 21st. Pulse strong, less rapid; respirations 38; coarse mucous râles heard throughout both lungs front and back. \mathcal{R} Ammo. carb., grs. ss., syr. senegæ, gtt. xx., aquæ menth. pip., \mathfrak{z} i. M. Take every three hours.

February 22d. Four greenish, watery dejections to-day. \mathcal{R} Tr. catechu., gtt. x., every three hours.

February 23d. Condition remains about the same. Five dejections to-day.

February 24th. Pulse rapid and feeble. Quinia increased to one grain every hour.

February 26th. Patient rapidly failing.

February 28th. Dead.

The temperature did not fall below 102° F. except on the morning of the fifth day, when it fell to 99.6° F., but that evening it was 103.8° F., and gradually rose until the day the child died, when it was 105.4° F.

CASE IX. A. H., aged six, entered the hospital February 18th. Sick four days with sore throat. Three days ago was languid and suffered on account of difficult deglutition; weakness and difficulty in swallowing still continue; diphtheritic membrane extends over posterior portion of right tonsil, covers whole of uvula and left tonsil.

February 19th. Membrane has not extended. Quinia sulph., one half grain, every three hours, was given. Membrane over right tonsil extending to uvula.

February 22d. Membrane over right tonsil size of little finger-nail; uvula clean; child bright and playful.

February 24th. Membrane has entirely disappeared.

March 2d. Discharged, well.

The temperature never rose above 100° F., and the pulse, which was 120 on entrance, on the third day was normal.

CASE X. J. E., aged six, entered the hospital February 18th. Sickness commenced last night with sore throat. Both tonsils swollen and inflamed; diphtheritic patch the size of the little finger-nail on the right tonsil.

February 21st. Membrane on both tonsils the size of the thumb-nail, with a narrow band over uvula and soft palate.

February 22d. Membrane very much diminished in size; a very small patch on right tonsil the size of a split pea.

February 23d. Membrane entirely disappeared.

February 28th. Discharged, well.

The temperature never rose above 101.2° F., and on the third day it was normal. The pulse, on admission, was 115, but on the third day it was normal.

CASE XI. E. G., aged twenty-five, entered the hospital February 20th. Sickness commenced five days ago with a chill, headache, and pain in the back. Right knee and leg swollen and painful, no pain in ankle or foot; bowels regular; no trouble with micturition; appetite poor; tongue dry, cracked, and covered with brown coating; slight difficulty in deglutition; membrane the size of a split pea on uvula, extending in a narrow line to both tonsils; temperature 101° F.; pulse 88; varicose condition of veins of right leg. Leg enveloped in a hot flaxseed poultice.

February 22d. Membrane covers uvula; tonsils clean.

February 26th. Membrane on tip of uvula, and a small patch the size of a split pea at either angle of its base; leg much swollen, and at points fluctuation can be detected.

February 28th. Membrane occupies only tip of uvula.

March 1st. Membrane has entirely disappeared; abscess in leg opened, and two ounces of pus discharged, giving much relief.

March 6th. Swelling and inflammation of leg much reduced.

March 12th. Discharged, well.

The temperature reached the normal line on the fourth day. The pulse never rose above 91.

CASE XII. K. S., aged thirty-five, was taken sick four days ago with headache, pain in back, a chill, and difficult deglutition. Bowels regular; no trouble with micturition; appetite poor; tongue heavily coated; right tonsil much enlarged; tonsils, uvula, and pharynx much injected; diphtheritic membrane the size of a thumb-nail over right tonsil.

March 4th. Membrane has extended to posterior part of right tonsil.

March 7th. Membrane much reduced in size.

March 9th. Membrane the size of a small lozenge.

March 11th. Membrane has disappeared.

March 18th. Discharged, well.

On the fourth day the temperature reached the normal. The pulse, which was 120 on entrance, was 90 on the third day, and never went higher.

IV. TWO CASES OF AMENORRHOEA.

These two cases seem to illustrate one of the recognized causes of amenorrhoea, namely, emigration.

CASE I. A. R., aged seventeen, unmarried, entered the hospital December 15, 1880. Menstruation began at the age of sixteen; was always regular every four weeks; flowed six days; only a slight headache the first two days of the flow. Mother died of phthisis. Always enjoyed good health. Sailed from Ireland last May; came by steamer; had a pleasant passage. Seven days before leaving Ireland was unwell, and has not menstruated since. Has a great deal of headache. Electricity was applied inside cervix uteri every day. She was given the following: R. Mistura ferri comp. ℥ii. t. i. d. R. Ext. gossypii ℥i. at night.

January 13th. Epistaxis every day for past three days.

January 28th. Menstruation commenced this morning.

February 1st. Ceased flowing this evening. While unwell the patient was kept in bed, and was not allowed to get up until three days after the flowing ceased.

CASE II. M. H., unmarried, entered the hospital January 17, 1881. Menstruation began at the age of eighteen; was always regular every four weeks; flowed two to three days; always had considerable pain; amount of blood lost was very small. Always enjoyed good health. No family history of phthisis. Sailed from Ireland May 15, 1880; came by steamer; had a pleasant passage. Was unwell last April 26, 1880. For the past three months has had headache most every day. Twice since last menstruation has had slight epistaxis. Electricity was applied inside cervix uteri every day, and the following medicine was given: R. Ferri sulph. gr. iiii. pulv. capsici. gr. i. quinine sulph. gr. i. ext. nux vomice gr. ss. M. Taken in pill form, twice after each meal. R. Ext. gossypii ℥i. at night.

January 26th. Flowed a little to-day.

January 31st. Pain in lower part of abdomen; tenderness on pressure over lower part of abdomen, especially marked over left ovarian region; severe headache; pain in left breast. Mustard paste applied on inside of thighs from knees to vulva.

February 9th. Pain in right breast and in lower part of abdomen. A mustard paste was applied to inside of thighs from knees to vulva. Patient had a hysterical convulsion during the evening. The pill ordered the 17th inst. was omitted, and the following

was substituted: R. Tr. aloes et myrrh. ext. ergot fl. aa gtt. xx., vini ferri ℥i. M. Taken t. i. d.

March 11th. Menstruation appeared. The flow continued four days, and was quite free. Patient was not allowed to get out of bed until two days after menstruation ceased.

In Case I. the pelvic organs were in a normal condition.

In Case II. the pelvic organs were normal except that the uterus was retroverted in the second degree, and the fundus was to the left side of the pelvis.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, M. D., SECRETARY.

MARCH 21, 1881. DR. J. ORNE GREEN read a paper¹ upon

DESQUAMATIVE INFLAMMATION OF THE EAR.

DR. C. J. BLAKE said that the thoroughness with which the pathology of the subject had been treated by Dr. Green left very little room for discussion, and that remarks must therefore be necessarily confined to a citation of cases in further illustration.

Practically considered the subject is one of considerable importance to the general as well as to the special practitioner, as it is for relief from deafness caused by accumulation of cerumen that patients most frequently apply to the family physician, and in any one of these cases the ceruminous accumulation may merely mask the principal cause of the trouble, and in place of a comparatively innocent obstruction, readily soluble in warm water, and easily removed by syringing, there may be found the masses of laminated epithelium described by Dr. Green, entirely insoluble in water, and affording no adequate hold for the forceps when attempt at extraction is made by that means; this is especially the case when the centre of the mass has become hardaceous. The difficulties attending the removal of a mass of this character are considerable, not only because of its consistency and insolubility in water, but also because of the tendency to rapid congestion and swelling of the lining of the canal as the pressure caused by the mass is relieved by its piecemeal removal. Under these circumstances the fatty character of the centre of the mass may be turned to account by boring into it with a cotton-tipped probe dipped in a strong potash solution, the result being the formation of a soap, which is easily removed by syringing; the alternate application of potash and warm water may be repeated until the centre of the mass is washed away, when it is comparatively easy to remove the investing layers of epithelium by means of the forceps.

THE CHARACTERISTIC APPEARANCE OF WOUNDS OF THE INTESTINES MADE DURING LIFE.

DR. WHITNEY showed some specimens of wounded intestines, and explained and illustrated the method of determining by post-mortem examination whether these were produced during life or not. His paper is published on page 54 in this issue.

In answer to a question Dr. Whitney said that in case of rupture from ulceration the protrusion of the

¹ See page 54 of this number.

mucous membrane would not occur because in these cases the mucous membrane is extensively destroyed and fastened to the muscular coats by inflammation before the outer coats are ruptured.

DR. MINOT said that the question whether a perforation had occurred before or after death, recalled the case of a historical personage, in which the eminent Dr. Littré diagnosed the disease nearly two hundred years after the patient's death.¹

Henriette d'Angleterre, sister of Charles I., who married the Duke of Orleans, brother of Louis XIV., died suddenly June 30, 1670, of poison, as was supposed at the time, and has been generally believed since. On the afternoon before her death, after dinner, the duchess, according to her custom, called for a glass of chicory water, which she had no sooner drunk than she was seized with agonizing pain in the pit of her stomach. Collapse accompanied by vomiting followed, and she died in nine hours. Dr. Littré chanced to find, in the *Bibliothèque Nationale*, the official report of the autopsy, in which it is stated that the stomach was healthy except that a small hole was noticed in the anterior wall *which was supposed to have been made with the scissors*. The cavity of the peritoneum contained turbid serum, soft lymph, and other signs of peritonitis, besides some castor oil, which had been administered to the patient before death. No satisfactory explanation of the death was furnished by the examination, but Dr. Littré justly remarks that the case was evidently one of perforating ulcer of the stomach, and that the signs of peritonitis, along with the presence in the peritoneal cavity of the contents of the stomach, prove that the opening occurred before death.

DR. MINOT also asked leave to read the following communication from Dr. George W. Snow, of Newburyport, which was of interest in relation to the absence of signs of external injury in the case reported by Dr. Whitney:—

On Monday, December 27, 1880, the boilers connected with a large shoe factory in Newburyport exploded, killing three men instantly; a fourth victim died from his injuries thirty-five hours after the accident. The following account of two autopsies may be of interest:—

CASE I. John R. B., thirty years old, was employed in a shoe shop, a large, three-story building, situated about one hundred feet south from the boiler house. Immediately after the explosion he was found in the second story of the building, lying on the floor, dead. On removing the clothing from the body no marks or bruises were found except two abrasions over the left breast. On opening the thoracic cavity I found a fracture of the sternum. A piece about four inches long was separated from its attachments to the clavicle above, and broken obliquely from above downwards. Portions of the cartilages of the second, third, and fourth ribs of the right side, and of the second and third ribs of the left side were broken. On removing the sternum I found the pleural cavity filled with blood, the amount estimated to be about twenty-four ounces. The pericardium was ruptured, and the heart literally torn to pieces. The right and left auricles and right ventricle were ruptured; the left ventricle alone remained intact. The left pectoral muscle was

bruised to a pulp and infiltrated with blood, though the skin was not broken externally, and the only marks about the seat of injury, or, indeed, on the whole body, were the two slight abrasions above mentioned. The lungs and abdominal organs were found in a healthy condition.

CASE II. Oscar S., eleven years old, was playing in a wooden building one hundred and fifty feet from the boiler house. I saw the boy within half an hour after he was injured, and found him extremely pale, pulseless, with short and difficult breathing, though perfectly conscious. He retained consciousness until within six hours of death, which took place thirty-five hours after the injury.

Autopsy fifteen hours after death. Rigor mortis well established. There was a bruise over the right eye, and evidence of a blow beneath the right scapula. On opening the abdomen I found the cavity filled with a bloody fluid, and on removing the liver discovered a deep fissure at the upper border of the right lobe, also a superficial transverse fissure about three inches below the deep one. The other organs were in a healthy condition.

DR. POST showed some DECALCIFIED CHICKEN-BONE DRAINAGE TUBES. These were soft and pliable, and were prepared by the method of Dr. Macewen, of the Glasgow Infirmary.

The tibiae and femora of fowls are scraped and soaked in diluted hydrochloric acid (one to five) until they are soft. The articular extremities are then cut off with a pair of scissors, and the contents of the medullary cavity are pushed through. They are re-introduced into fresh dilute acid, and left until they are somewhat softer than is desired, as they afterwards harden somewhat in the carbolic solution. They are then soaked in carbolic acid and glycerine (one to ten) for fourteen days, when they are ready for use. They are then translucent and elastic, and in contact with granulations are absorbed in about eight days.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. E. SWAN, M. D., SECRETARY.

A CASE OF HYSTERO-NEUROSIS.

DR. BIXBY read the case, which was published in the number of the *JOURNAL* for June 30, page 606.

DR. SINCLAIR remarked that he had not taken interest in this class of cases, that he avoided them. He had found in the male sex symptoms not differing from those of the female.

DR. C. E. STEDMAN asked Dr. Bixby if he could judge what would have been the result in his case if local treatment had not been employed, and stated that he now had the case of a *man*, who had been too actively engaged in business, with pain in the back, weight at the top of the head, numbness of the spine, and other symptoms like those complained of by women with cervicitis, flexions, etc.

DR. HOSMER asked Dr. Stedman if different causes produced the same results, namely, overwork in the man and nothing to do on the part of the woman.

DR. LYMAN said he agreed with Dr. Minot that the patients required to be "bullied," but by some other than the family physician. He was aware of several instances where such treatment as would not

¹ Henriette d'Angleterre, Belle Sœur de Louis XIV., Est Elle Morté Em poisonnée? Par E. Littré (*La Philosophie Positive*, September, October, 1867, Paris).

have been submitted to from the family physician, had been for the time being very effectual. Dr. Lyman's own experience was that patients relapse on return to the freedom and indulgences of home; but in one instance in which he could do nothing with his patient this Philadelphia treatment had great influence, and she was permanently cured. Hystero-neurosis, he said, applied to cases of reflex action, where there is some generally unrecognized local disease, the cure of which is followed so suddenly by relief of the reflex and apparently principal disorder as to make it probable that the local disease was the chief factor in the general condition. There were, in fact, a great many cases where physical disturbance caused no local symptoms, but the cure of which gave immediate relief to the nervous disturbance in perhaps distant organs. Dr. Lyman referred to a patient with retroluxion, who every month for a few hours had pain in the back of her head and a boring pain through the temples. When the uterus was retroverted the pains became more severe, — once so severe as to make it quite a serious matter, — while restoration of the uterus gave immediate relief. Another case was one in which a peculiar cough, resisting treatment by himself and others, was immediately relieved on his discovering and rectifying a displaced uterus. In this case the cough continued for many weeks. A peculiarity of it was that it came only at night, keeping the patient awake till two or three o'clock in the morning. Dr. Lyman referred to the analogy of ear-cough, caused by some conditions of the ear, and relieved by local treatment, such as syringing out the meatus, or blowing out the middle ear. He gave the case of a patient with cough and dyspepsia, who had lost the ability to walk. A pessary relieved the cough and dyspepsia, and restored the locomotion, and that so suddenly after long and ineffectual treatment of other kinds as to make the cause and effect perfectly apparent.

Dr. Hosmer said there were two classes of cases which should be kept distinct, and asked if exercise were the cure for all. He remarked that broken-down women break down slowly and recover slowly. His plan had been absolute rest, good diet, making comfortable, passive exercise, and these could be instituted early. Bullying he thought better adapted to those cases which are purely hysterical, persons thinking of themselves being likely to have exaggerated estimates of the importance of their own symptoms and sensations. He insisted that the difference between these two classes should be carefully borne in mind.

Dr. Lyman said there was a large class of cases with symptoms which are traceable to local disturbance, hystero-neuroses, distinct from hysterical asthma, as decidedly reflex as the vomiting of pregnancy.

Dr. Blake remarked that investigations upon subjects of uterine disease had thrown much light upon the cause of hysteria. He referred to the case of Miss H. Wostenholm, who had made the circuit of all the hospitals, here and abroad, and had been the subject of treatment in most of them. It was supposed she had a phantom tumor. Etherization caused her abdominal swelling to disappear. A corset was once employed to compress the abdomen, but the woman declared the tumor was still there, resisting the corset. She was once the subject of an exploratory incision. She finally committed suicide, and an autopsy made by Dr. Blake and Dr. Bixby revealed both ovarian and uter-

ine disease, — more than she was credited with during life.

PLURAL BIRTH WITH COMPLICATION.

Dr. Brown reported a case of twins occurring in a primipara, a small person, twenty-five years of age. The first child was delivered by the head, the occiput at the left acetabulum. On making an examination the second child was found presenting by the lower extremities, one foot being recognized through the membranes within the os. After a few minutes' delay the membranes were ruptured, and a foot brought down. An attempt to bring down the other foot was unsuccessful, from some impediment which could not at that time be determined; but on bringing the breech to the external opening the cord was found tightly stretched from the umbilicus to the ankle, round which it passed. The knee was pressed firmly against the breast. On making careful examination no trace of rupture of external organs was found. The uterus contracted somewhat slowly. The placenta were united by their edges, the cords entering at a distance of three inches.

Recent Literature.

Minor Surgical Gynecology. A Manual of Uterine Diagnosis and the Lesser Technicalities of Gynecological Practice. By PAUL F. MUNDÉ, M. D. New York: William Wood & Co. 1880.

Despite the numerous works on gynecology which have of late appeared, Dr. Mundé's book enters a field hitherto unoccupied, for the minute details of the manipulation necessary to examine and treat the everyday cases of the general practitioner can receive but the most limited attention in a general treatise on the diseases of women, and with this the physician who has had no special training for such work is dissatisfied. It is, then, just how to deal with ordinary cases that it is the purpose of the author to set forth. We recognize the fact that this is best accomplished by practical clinical instruction, a method, however, often impossible, and whose best substitute must be a clearly defined, minute, and well illustrated description of the processes. This is abundantly furnished in the volume before us.

Owing to cheapness of paper and printing the book is far less attractive in its appearance than some of those which have recently preceded it. But one becomes gradually tolerant of this, and perhaps the lessening in expense to the practitioner may be a sufficient offset to him.

The modifications of introducing and holding the Sims speculum are, we think, less desirable than the method followed by Sims and Emmet. We have found that the inexperienced nurse, or the friend of the patient called in for the occasion, succeeds best by holding it in the modified method here described, but that the trained nurse who has learned to extend the hand properly after the original method of its use, receiving the weight of the speculum and thereby the resistance of the perineum on the hand and wrist, has the instrument in much steadier control, and is able to continue it for a longer time. The figure of the modified method on page 76 seems confusing, apparently requiring the patient to lie in the right instead of the usual left, semi-prone position, in order to bring the right and left hands, as shown, to their proper places.

The method of seizing the anterior lip of the cervix (page 79) by hooking the tenaculum into the endocervical membrane must cause more pain than its introduction into the vaginal mucous membrane covering the cervix.

The position for examination shown as the correct one (Fig. 60) could, in our judgment, be improved by placing the patient more diagonally upon the table, that is, by moving the head, right shoulder, and arm farther to the edge opposite that where the hips are. In the figure the hips are right, but the shoulders are too near the centre of the table.

We cannot at all agree with the author in his preference for the introduction of the sound by the sense of touch. In the hands of the expert there is little or no objection to it, but Dr. Mundé's book is emphatically, he says, designed for the general practitioner, and by the general practitioner we consider it much safer that the probe should be used for all purposes except the determination of the calibre of the canal; even then its use should be preceded by the passage of the probe, and the sound then curved to correspond to the probe. Both these instruments are unquestionably most safely used through the Sims speculum. With the patient on the back the sound passed into the uterus by the ordinary practitioner offers too great a temptation to test the mobility of the organ. Violence may thus be done to the endometrium, or, worse still, inflammatory action outside the uterus be established. Any question as to the mobility of the uterus is most safely settled by bimanual examination.

The author's treatment of the subject of pessaries. Section XII., is admirable, and a close observance of the rules given for their use and care would, we are sure, lead to much greater efficiency in the cases requiring them.

A Text-Book of Practical Histology, with Outline Plates. By WILLIAM STIRLING, M. D., Professor of the Institutes of Medicine in the University of Aberdeen. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1881.

This is a handsome quarto volume containing thirty lithographic outline plates, and in outward appearance, at least, differs widely from the numerous practical histologies that have appeared in the last few years. The purpose of the work, we are told in the preface, is a double one: "first to give plain, definite, and precise directions for the preparation and examination of the animal tissues; and, secondly, to ensure that the student executes a drawing of the majority of the microscopic specimens which he makes for preservation." Now the first purpose is that of several other works, and if it were the sole one would not justify a new publication, for some of those that we have are perfectly satisfactory. The directions for work, and the plan of the course, show little that is new, but they are plain, practical, and good.

The second purpose of the book is, therefore, the one on which its claims to originality rest. The author tries to combat the student's well-known unwillingness to draw anything except caricatures by giving outline plates of the various elements and organs, the details of which the student is to fill in with crayons or water-colors. The idea is a very good one; the only question is whether it can be put into application.

This depends largely on the instructor. The outlines are very well executed. Although, as has been said, this plan of filling in outlines is the only thing essentially new in the book, we look upon anything that will encourage drawing as so valuable that we are inclined to welcome this work as a useful aid to instruction, though it be no great addition to histological literature.

T. D.

Dysmenorrhœa. Its Pathology and Treatment. By HEYWOOD SMITH, M. D. London: J. and A. Churchill. 1881.

We are glad to see that the author treats dysmenorrhœa as the symptom of a pathological condition, not, as some of the text-books would teach, uniform in character. Various and very different pathological conditions, or perhaps some general disease, or the state of the blood, may, any one of them, be sufficient to produce the symptom which it is the province of the book to consider. From its title we were led to expect a much fuller description and analysis of the pathological conditions giving rise to dysmenorrhœa, but we fail to find this part of the work as thoroughly treated as in many of our text-books.

Most of the treatment recommended is cautious, conservative, and decidedly good. We are the more surprised, therefore, to find the author so universally advise the use of intrauterine stem pessaries for flexions of the uterus.

SIR ISAAC NEWTON ON THE VALUE OF SLEEP. — The following quaint letter from Sir Isaac Newton to a medical friend has only been recently published: —

LONDON, December 15, 1716.

"DEAR DOCTOR — He that in ye mine of knowledge deepest diggeth, hath, like every other miner, ye least breathing time, and must, sometimes at least, come to terr; alt for air.

"In one of these respiratory intervals I now sit doune to write to you, my friend.

"You ask me how, with so much study, I manage to retene my health. Ah, my dear doctor, you have a better opinion of your lazy friend than he hath of himself. Morpheous is my best companion; without 8 or 9 hours of him yr correspondent is not worth one scavenger's peruke. My practizes did at ye first hurt my stomach, but now I eat heartily enow as y' will see when I come down beside you.

"I have been much amused by ye singular *φαισμενα* resulting from bringing of a needle into contact with a piece of amber or resin fricated on silke clothe. Ye flame putteth me in mind of sheet lightning on a small — how very small — scale. But I shall in my epistles abjure Philosophy whereof when I come down to Sakly I'll give you enow. I began to scrawl at 5 mins frm 9 of ye clk. and have in writing consmd 10 mins. My Ld. Somerset is announced.

"Farewell, Gd bless you and help yr sincere friend,

"(Signed) ISAAC NEWTON.

"To Dr. Law, Suffolk."

No. 4 PARK STREET, BOSTON, MASS.

CREMATION.

A LARGE meeting was recently held at Bologna to advocate the introduction of cremation instead of burial as a means of disposal of the dead of the town. Many physicians are reported to have been present, and to have taken an active interest in furthering the proposition. It seems probable that Bologna will before long be provided with a public crematory, as Milan and Lodi in the north of Italy now are.

In the cremation hall just outside the city of Gotha in Germany, which is one of the best arranged of those thus far established, fifty-two bodies, five being those of women, have, since its erection, less than three years ago, been subjected to the process; of these bodies one was sent from so great a distance as New York, and one, at least, from England.

We have not at hand the exact number of bodies which have been reduced in the furnace at Washington, Pa., but believe it to be still quite small. To overcome existing prejudices against such an innovation upon old habits and customs it is essential, not only that the scientific process of combustion should be as complete, as rapid, and as imperceptible as possible, but also that the building and its surroundings should be attractive and in keeping with a solemn ceremony. The buildings at Milan and Gotha answer these requirements, the latter place, however, has the additional advantage of being provided with a Siemens' incineration apparatus in which the process of reduction takes place in superheated air, the body not being brought at any time in direct contact with the flames. Outside the cremation hall is an open portico in which the cinerary urns are arranged. Within is a hall where the religious ceremony, when such is desired, may be performed, and where the body awaits its removal to the furnace. For this nine hours of preliminary preparation are required. The air in the receptacle where the body undergoes incineration is heated to 600° Réaumur, and two hours elapse from the commencement to the completion of the process before the ashes are collected. Of these the average body of a man yields about six pounds, that of a woman about four. Only the officials and one or two of the nearest relatives are admitted to the chamber underground in which the furnace is situated. The cost of the process at Gotha is about twenty-five dollars.

At Milan the entire process may be watched through a small window; and the cost of conversion by the Gotha furnace, the one there in use, is only about one

dollar; in this apparatus, however, the body is subjected to direct contact with the flames. Venini's furnace has the same disadvantage, and is besides quite complicated, but it performs its work with rapidity and thoroughness.

A furnace constructed by Dr. C. W. Siemens was referred to by Sir Henry Thompson in his article on Cremation, in the *Contemporary Review*, which converted a body weighing two hundred and twenty-seven pounds, placed in a cylindrical vessel seven feet long, by five or six in diameter, the interior being heated to 2000° F., into five pounds of ashes in fifty-five minutes.

It is evident from the progress already made that the question of the best methods of cremation will receive a pretty definite and satisfactory solution long before the sentimental considerations involved are appreciably affected by argument or example.

Being convinced that in regard to this matter time will prove the most successful pleader, we wish in the short space left us to direct our readers' attention to the consideration of one of the not least important of the possible uses of cremation into which sentiment does not enter. In a small volume on Cremation recently published by Dr. Bermingham, of New York, a chapter is devoted to the Cremation of Dead Animals and Garbage, from which we make the following extracts:—

Although a moment's consideration will suffice to prove that this method of ridding communities of a large proportion of disease-producing matter is indubitably the most expeditious and safest yet proposed, nevertheless it has not come into general use.

The remarks of Sir Henry Thompson, in regard to the economical aspects of cremation, although applied to human remains, would more fittingly apply to the bodies of dead cattle, since it could not be urged against utilizing the bones of animals that it was indecent or in any sense shocking to the sensibilities of the most sensitive, but, on the contrary, would naturally be considered praiseworthy economy. He states "that London was computed, by the census of 1871, to contain 3,254,260 persons, of whom 80,430 died within the year. I have come to the conclusion, after a very carefully-made estimate, that the amount of ashes and bone-earth—such as is derived from perfect combustion—belonging to and buried with those persons is by weight about 206,820 pounds. The pecuniary value of this highly concentrated form of animal solids is very considerable. For this bone-earth may be regarded as at least equivalent to at least six or seven times its weight of dried and unburned bones as they ordinarily exist in commerce. The amount of other solid matters resolvable by burning into the gaseous food of plants, but rendered unavailable by burial for say fifty or a hundred years or more, is about 5,581,000 pounds, the value of which is quite incalculable, but it is certainly enormous.

This estimate is for London alone; for the United Kingdom multiply by nine in order to obtain the amount of valuable economic material annually diverted for a long term of years from its ultimate destiny by our present method of interment.

"This necessitates the purchase from other countries of bones amounting to half a million pounds sterling per annum."

It is very evident, from the above estimate, that the utilization of diseased cattle would effect no inconsiderable saving to a country, regardless of the amount that would be saved from the prevention of disease that would ensue from the adoption of such a plan.

As to the manner in which the bodies of dead animals might be burned, Dr. Beals suggests, in the *British Medical Journal*, that until suitable apparatus was devised the gas-works of towns could be made available by severing the animals into pieces and throwing them into the retorts, when almost instant combustion would take place, and the products be utilized.

It is certain that cremation of dead animals would be, both from a sanitary and economical view, an incalculable benefit. In an age when waste products of all kinds are made a source of revenue, it is remarkable that such a feasible and possibly prolific factor in the production of wealth should have been overlooked, or at least exist in such an undeveloped state.

What shall be done with garbage? is a question the solution of which has long vexed the executive power of street cleaning bureaus, and given the public, through the medium of the daily journals, a constant cause of complaint. The present plan of collecting it periodically, or rather spasmodically, and dumping it into the sea (the plan in operation in New York, involving great expense) is notoriously inefficient and abortive.

Among the plans suggested as a substitute for the present unsuccessful one cremation is advocated by many, and will, we believe, eventually prove the only practicable solution of the question.

The burning of the more easily combustible garbage should be individually effected in the place where it is produced, while that which could not be thus disposed of could be collected and burned by the proper authorities at a much less expense and with far greater efficiency than is the result of the present extravagant and ridiculously inoperative method.

We are conscious that the subject of burning garbage is an old story in New York city, and though its advisability may be admitted, the question of its adoption is complicated by that disgraceful blight on our city's sanitary progress, the influence of unprincipled politicians.

But the question of the best disposition to be made of garbage is not merely a local one, and should engage the attention of families and communities and armies in every land. The obstacles which interfere with the public adoption in New York do not exist in private families, and in many cities, communities, and armies. Wherever, therefore, this plan is feasible it should be tried, and if this is done a step in the promotion of hygiene will have been taken, whose beneficial results will constantly extend, and the saving—in life, and public and private expenditure—to the State and the individual will be incalculable.

MEDICAL NOTES.

—The number of applicants for the degree of doctor of medicine at the annual commencement at the Harvard Medical School, June 29, 1881, was eighty-five. Of these sixty succeeded in fulfilling all the requirements, and twenty-five failed to pass in all the examinations. There were four applicants for the degree to be conferred upon students attending the four years' course, but no one candidate was able to satisfy all the examiners. The quality of the graduates of this year may be inferred from the fact that thirty-two of the sixty have received literary or scientific degrees before beginning their medical education.

—The Wilmington (Del.) Board of Health, at a meeting, July 8th, decided to request and instruct all churches, Sunday-schools, and other organizations to hold no more meetings until further notice, owing to the alarming spread of the small-pox, and to advise that no more excursions, etc., take place this summer. The disease has not yet assumed an epidemic form, but its spread has been remarkable within the past few days. Action will at once be taken to prevent any further spread of the disease and to stamp it out altogether.

—The following paragraph from the daily press shows a growing appreciation of sanitary necessities:—

More than forty cases of scarlet fever having appeared at Keswick, in England, the medical officer traced their cause to a dairy from which the infected families received their milk. A single case had been brought to a house next to the dairy. The English are nearer to a successful solution of the problem how to deal with infectious diseases than we, in that almost every town and village has its medical officer, who is obliged to trace the infection to its originating cause, if possible, to isolate all cases of contagious fever, and, no matter what the rank of the patient, to compel the abandonment of the house in which the case has occurred, and its thorough disinfection. In all these actions he has the law to sustain him. With regard to typhoid and scarlet fever, both lately have been repeatedly traced to dairies. Exactly how the poisonous germs are communicated through the milk has not yet been discovered, but of the fact that they are so disseminated through whole neighborhoods there can be no doubt.

—I thank you for the copies of Sir Charles Hanbury's poetry, which extremely entertained me. I find tar-water has succeeded to Ward's drop; it is possible by this time that some other quackery has taken the place of that; the English are easier than any other nation infatuated by the prospect of universal medicines; nor is there any country in the world where the doctors raise such immense fortunes. I attribute it to the fond of credulity which is in all mankind. We have no longer faith in miracles and relics, and, therefore, with the same fury, run after recipes and physicians. The same money which, three hundred years ago, was given for the health of the soul, is now given for the health of the body, and by the same sort of people, women, and half-witted men. In the

country, where they have shrines and images, quacks are despised, and monks and confessors find their account in managing the fear and hope which rule the actions of the multitude.

My cure for lowness of spirits is not drinking nasty water, but galloping all day, and a moderate glass of champagne at night in good company; and I believe this regimen, closely followed, is one of the most wholesome that can be prescribed, and may save one a world of filthy doses, and more filthy doctor's fees at the year's end. — *Letters of Lady Mary Wortley Montagu.*

—The committee engaged in organizing the exhibition to be held at South Kensington on and after July 16, have agreed to set apart a considerable space for the purpose of illustrating the various appliances in ordinary use for the treatment of the sick at the chief London hospitals. Their request to exhibit a bed with its full equipment of ward furniture, along with splints or other apparatus in common use for fractured limbs at each hospital, has been readily acceded to by the governing committees of the twelve hospitals associated with medical schools, as well as by the Medical Department of the Army and Navy and Local Government Board. It had been felt that although the surgical appliances referred to would be best shown on the living model, it would have been unwise to introduce such in a miscellaneous exhibition, and considerable difficulty has been experienced in providing efficient substitutes, since lay figures are expensive and unobtainable in sufficient number from commercial sources; while the *papier-maché* figures in common use in shops are without joints, and are otherwise ill adapted for the purpose indicated. This difficulty has now been surmounted by the result of an appeal made to several members of the Royal Academy for the loan of their lay figures during the time the exhibition is open. Sir F. Leighton, Messrs. Milais, Calderon, Leslie, Frith, Yeames, etc.,—in fact, all the leading academicians,—have responded so readily to the request made to them that the number of applicants for relief considerably exceeds the number of beds at the disposal of the committee. It is proposed to have the hospital appliances arranged in saloons in the Albert Hall, contiguous to and in direct communication with the exhibition buildings, and it may be confidently predicted that the department, which will possess a scientific and humanitarian interest apart from the character of the rest of the exhibition, will prove especially attractive to foreign and country visitors, who will thus have an opportunity of seeing within small compass what is done at the best hospitals, without having to make a tour of the metropolis. — *Medical Times and Gazette.*

—Our readers may recognize some well-known names, some more easily than others, in the *British Medical Journal's* announcement of distinguished Canadian and American visitors expected to visit the forthcoming International Medical Congress, namely: Drs. Osler and Howard, of Montreal; Dr. Gordon, of Portland; Drs. Carter, Bigelow, and Lyman, of Boston; Drs. S. Gross, Jr., T. Morton, Horatio Wood, Theinson, Goodall, W. W. Keen, Cohen, and J. Mims

Hay, of Philadelphia; Dr. Yandell, of Louisville; Dr. Hutchinson, of Brooklyn; Drs. Austin Flint, Fordyce Barker, Otis, Sayre, Weir, Metcalf, Saunders, Lefferts, Lincoln, Bosworth, Jacobi, and Goodville, of New York.

—Brill's sea-water baths at Brighton have long enjoyed a high reputation, and now a company, entitled Brill's Sea-water Baths, London, and Savoy Mansions Company, has been formed to supply for London "tepid sea-water swimming baths" for gentlemen and for ladies, "hot sea-water baths," and "douche, vapor, and shower baths." A site has been obtained for the establishment on the Thames embankment, on the western side of Waterloo Bridge; and the sea-water is to be brought to the very doors of the baths by steam-vessels especially constructed for the purpose. — *Lancet.*

—It will have been seen that the society for the total abolition of biological investigation by experiment upon living animals has now enlisted the active support of Lord Coleridge, who invests it with a special weight by calling the meeting at his house, described in the reports as the residence of "the lord chief justice of England." The current misstatements were glibly repeated, and it is time that papers setting forth the truth were made more accessible than they now are. — *British Medical Journal.*

—A report by M. Rendu on the maternity department of the Tenon Hospital, in Paris, shows that, notwithstanding all possible precautions, as well as the isolation and the good arrangement of the buildings appropriated to that use, an epidemic of puerperal fever has broken out, and sixteen women have been attacked by it. M. Rendu has discovered that the wind, during the days in which the fever made its appearance, came from the east, that is to say, from the post-mortem room. — *British Medical Journal.*

—The following appreciative notice of the number of the JOURNAL issued on the centenary of the Massachusetts Medical Society is taken from the *Lancet*:—

The Massachusetts Medical Society has just been holding its centennial anniversary at Boston, when an address was delivered by Dr. Samuel Green, and one by Dr. J. Collins Warren. The Boston Medical and Surgical Journal for June 8th is wholly devoted to this celebration, and contains not only portions of Dr. Green's address, but many articles, extracts, and facsimile reproductions of antiquarian interest, illustrative of the period when the Society was first established. It reproduces a memoir of the venerable founder of the Society, Dr. Edwin Augustus Holyoke, who died in 1829 at the age of one hundred years, and a silhouette of him appears as a frontispiece to the journal, with a facsimile of the toast, "The Massachusetts Medical Society," written out by himself at the public dinner given in his honor by the faculty of Boston, Salem, and vicinity on his centennial birthday, August 13, 1828. The whole number is very interesting, and is an admirable instance of journalistic enterprise.

—The total of deaths in New York City is increasing rapidly from week to week. Deaths under five,

and deaths from diarrhoeal diseases occupying the prominent places in the returns.

— The twenty-fifth anniversary of Dr. Rudolf Virchow's appointment as Professor in the University of Berlin is to be celebrated on October 13th.

— A millionaire of Cincinnati is said to own the Eclectic Medical College of that city, and also John Robinson's Circus.

— In the case of seventy-five out of ninety-six decedents for whom burial permits were issued in Cincinnati one day last week the excessive heat was returned as the cause of death. Forty-one deaths from heat were returned in one day.

— The degree of LL. D. was conferred by Yale College, at its late commencement, upon Professor Austin Flint, of New York.

Miscellany.

MODERN SENSITIVENESS.

MR. EDITOR.—When the King of France was dangerously wounded by a lance point deeply imbedded in his upper jaw, Ambrose Paré, who in the light of the surgery of the day was in doubt whether the extraction might not cause death, ordered out four soldiers, thrust lance points in their faces, and operated on them, testing the best method of extraction.

Public opinion would not allow Dr. Bliss to test in the back of Guiteau (though a confessed assassin) the penetrating power of his own pistol, even if it were certain that the President's life could be saved by such an experiment. Yet it must be confessed that in some respects this would be more charitable than slowly to play with the disordered vanity of a fool, as Colonel Corkhill seems to be doing, and fully as useful as to allow the newspaper men to make a sensation of one who appears to be delusionally insane, thereby apparently exciting the emulation of other similar crazy people throughout the country. It is, however, surprising that a much-needed investigation on cadavera in regard to the course of projectiles and the penetration of pistol balls should excite a thrill of horror among the "sensitive and sensible," to use the excellent expression of the *Boston Herald*. If a thorough study be made on cadavera of the effect of pistol shots under a variety of circumstances and conditions, and frozen sections be made and photographed, the surgeon would have much more to guide him in diagnosis than now is the case. Any one who should attempt this, however, would apparently be in danger of being ostracized by the "sensitive" and perhaps also the "sensible."

Truly, advances in science are hardly won. The physician is taunted with knowing little, the community looking rather at what remains to be studied than at what has been won; and yet if he searches after truth in the only way open to him the community protests and regards him as an enemy of mankind. In the days of Pasteur we have people who seek to do away with vivisection; after Virchow's labors the greater part of the community regard autopsies as profanation; and after a war which has shown to the world the usefulness of surgery, our operators are hampered in their experiments on cadavera as to the best method of saving life and limb by the popular shrinking from a proper anatomy act.

I regret to see that your esteemed daily contempo-

rary, the *Boston Herald*, joins the throng in regarding those who earnestly strive for the acquisition of knowledge which they have reason to hope may be of use as violating the rules of common decency, and I trust that when its editor is pistolled by a stalwart — and the well-known independence of his views may yet expose him to such an accident — he may fall into the hands of a surgeon who has had ample opportunities for dissection, and who has learned all that can be learned by experiment *in corpore vili*.

Such sensitiveness needs to go but a little further before it will cry out against all dissection; and as surgeons must exist, it would simply be raising up a crowd of inferior men who would be willing to practice surgery without adequate training. The surgeon must then learn to operate by doing the necessary operations upon such patients as fall into his hands, rather than by previous experience upon the cadaver. The following is the paragraph in the *Herald* (July 13, 1881) to which I refer:—

"We are sure that all sensitive and sensible people will sympathize with the vigorous protest of John Swinton, in the New York press, against the horrible pistol practice upon dead bodies by a professor in Bellevue hospital, with a view to ascertaining the probable course of the bullet in the body of the President. Friendless patients who die in the public hospitals perhaps have few rights, after death, which so-called 'science' is bound to respect, but it ought to be possible for the public to protect the bodies of these unfortunates from needless outrage. A hundred shots might enter living human bodies at the precise point where the President was wounded, without taking the same course, or producing similar results. So much depends upon the position of the assassin and his victim; upon the cartridge and ball, the clothing, the quality of the bone and muscle, and a dozen other conditions. To suspend an inanimate body by the neck, destitute of clothing, and attempt to decide upon the probable course of the ball and nature of the wound in a case differing in every essential particular, is something more than folly. It is an outrage which Mr. Swinton does not characterize too severely, and which cannot be stopped too soon for the credit of the institution. SURGEON.

Boston, July 14, 1881.

REVELATIONS UNDER ETHER.

MR. TOM BIRD, instructor in the use of anesthetics at Guy's Hospital, confides to the *Lancet* the distressing freedom of speech to which patients have exposed him when under the influence of ether:—

My first case of ether mania was that of a man between forty and fifty years of age, who had undergone a simple operation for which he required to be deeply anesthetized. Chloroform was denied him,—reason unassailable. Gas and ether had been used, the operation lasting from ten minutes to a quarter of an hour. For two hours he literally confessed; as he expressed it in the evening, "I knew what I was saying perfectly. I knew that I ought not to say it, but I could not help it, and you ought not to have left her (the nurse) in the room." He was right, but I did not know why until I met with my second case some eighteen months afterwards. It was that of a young married woman, a hospital patient, whom I saw from half an hour to three quarters after the operation. She was recounting to her mother (not present), in the clearest tones, subject matter that I do not think she would have ever confided if conscious; it was a subject that had evidently been laid by in memory. For a quarter of an hour I tried to divert in every way her attention to her present condition, insisting that her mother was not present, without the slightest

avail; she was totally oblivious of everything but her story. The patient was a lady of education and refinement, and her language had not the slightest fault in its expression, but her bedroom was a "palace of truth."

There is not the slightest connection between the symptoms of these two cases, and the ramblings of chloroform, which are disconnected, illusory, and easily diverted, occurring mostly during administration, or the gibberish of methylene bichloride,—the latter is not even noisy, but this ether mania is a noxious thing and the lesson I would draw is that the patient should be left only in the care of a discreet and responsible nurse until all self-control returns.

BROOK STREET, W.

OUT-PATIENT ABUSE AT THE MASSACHUSETTS GENERAL HOSPITAL.

THE new system of admission of out patients at the Massachusetts General Hospital, of which notice was formally given, has now been in operation three months. The result is considered very satisfactory. No great number has been excluded, but enough to confirm the previous impression, that positive imposition was practiced. During a corresponding quarter last year (1880) 4556 patients were admitted; of this number 3033 were residents of Boston, 1523 were resident outside of Boston. During the three months ending June 30, 1881, 3638 were admitted; 2321 were residents of Boston, 1317 were from outside of Boston. As these statistics show, there has been no marked relative decrease either amongst the residents or non-residents. The effect upon the Hospital has not been to diminish the number of admissions, as the number admitted during April, May, and June exceeded the number admitted during the corresponding months of last year by 42. Neither was the class of patients of the poorer class, as the number of paying patients exceeded those of the corresponding quarter of 1880 by 40. During the three months, 323 applicants seemed to be questionable cases for free treatment; investigations showed that 238 were deserving and 155 undeserving. The results are quite satisfactory and it is believed that further experience and more careful discrimination will allow further elimination of the undeserving class.

FOURTH OF JULY CELEBRATIONS AND THE SICK.

MR. EDITOR.—While lying awake on the night of the third of this month, I was reminded by the noise of an old idea that a civilized community owes protection to its members against unnecessary noise, as against other evils that can only be controlled by the public as a whole; and that we in the large cities have outgrown the propriety, if there ever was any, in the present style of celebrating the Fourth of July.

If people choose to risk gunpowder accidents that is their own lookout, for the sinner is apt to be the victim; and if the Fire Departments choose to risk giving their forces sharp exercise in July, that is no concern of a medical journal; but the unnecessary noise, and wantonly depriving the sick of their sleep, is a matter in which the profession may well take an interest. The writer believes that he has seen death hastened by the endless noise for two nights and a day,

and every physician must have seen the dread with which sick people sometimes look forward to thirty-six hours of racket.

The amount of distress from loss of sleep in babies, just at the beginning of hot weather, and of consequent fatigue for their mothers, must be worth the attention of the Society for the Prevention of Cruelty to Children.

If the death roll of the Fourth of July could be compared with that of the revolutionary regiments, it would, I think, be seen that peace has its horrors as well as war, with a difference: the one necessary and glorious, the other unnecessary and silly.

The writer would be sorry to see the celebration, or the military celebration, of the Fourth abandoned; but believes it very easy to substitute something more adapted to a large city than tin horns or Chinese crackers, which can be in place nowhere except at the circus; and he believes that processions with music should not pass through the streets either before the tired workers of the town are awake on July 4th, or after they are in bed, as is done before every presidential election. Will our Board of Health consider the matter?

E. M. B.

TYPHOID FEVER IN CHILDREN.

IN an article in the *London Practitioner* for June, by Dr. Henry Ashby, physician to the hospital for sick children in Manchester, we find the following statement, in regard to typhoid in children:—

Typhoid fever in children does not differ very materially in its course, pathology, or treatment from the typhoid of adults. There are, however, a few points of interest in connection with the disease as it affects children that are perhaps worth noting down when a series of cases are fresh in the memory. It has been pointed out by several writers that before puberty the disease, as a rule, is seen in a milder form than after that epoch; and that, as a broad rule, children are more susceptible to its influence than adults, especially those of maturer years.

In considering the question of children suffering from the disease in its most favorable form, we shall not be very far wrong in taking the mortality as our guide. The mortality for all ages from typhoid fever is from fifteen to twenty per cent., according to Murchison and other authorities. Now Barthez and Rilliet, Hillier, Gerhardt place the mortality of children of ages from two to twelve at ten per cent. In our own hospital during the last nine years, two hundred and sixty-five cases have been treated, with twenty-one deaths, making a mortality of nearly eight per cent. These facts point pretty certainly to the conclusion that a child contracting the disease has a much better chance of having it in a milder and less complicated form than if he waited till puberty was passed and manhood reached before taking it.

The typhoid of children more often aborts, that is, runs a course of two weeks instead of three or four, than the typhoid of adults. That such cases are in reality typhoid in character may be known from the presence of spots, rounded abdomen, remittent temperature, etc., and their occurrence in houses where undoubted cases have recently occurred. In other cases the temperature is characterized by well-marked remissions of three or even four degrees all through its course, but more especially after the middle of the

second week. Such cases are rarely actually ill; in the morning especially they will sit up in bed, thread beads, play with dolls, and, but for a heavy look about their eyes and a glance at the temperature chart above their beds, it would be difficult to persuade one's self that they were suffering from any febrile disease. As a rule, such cases are not accompanied by much diarrhoea, do not relapse, and make a favorable recovery. On the other hand, cases will occur as severe, and accompanied by as much weakness and prostration, as any that may be seen in adults.

POST-MORTEM EXAMINATION ON PROFESSOR SKODA.

THE *Lancet* gives the following details of the post-mortem examination on Professor Skoda:—

Skoda had expressed a wish that his body should be carefully examined in all parts, and had asked Professor Heschl to perform for him this last service. Heschl, however, died some weeks before Skoda, and the news of his death was received by the latter with the exclamation, "Now some one else must examine me." The task was intrusted to Dr. Chiari, and the examination was made on the 14th of June, in the presence of Schrötter, Kohn, Chrastina, and Kraus. The following is a condensation of the official account: The body was thin and pale, and the lower limbs œdematous. The skull was of moderate thickness, the bone and dura mater being adherent. The arachnoid was somewhat opaque over the convexity, and separated from the convolutions by a considerable quantity of serum. The larger arteries were degenerated and calcified. The brain, including the meninges, weighed thirteen hundred grammes (forty-five ounces), considerably below the average in weight; indeed, adult male brains of lighter weight are not often met with. The convolutions were of the ordinary configuration, the sulci being wide. The cerebral substance was somewhat diminished in consistence. The ventricles were rather large, and filled with clear serum. There was no local lesion. The mucous membrane of the air-passages was reddened. On the right side there were extensive pleural adhesions, and slighter adhesions on the left side. In the apex of each lung were black pigmented radiating scars. The pulmonary tissue was elsewhere somewhat congested and œdematous. The bronchial glands were indurated, and filled with black pigment, and in one of them the right recurrent laryngeal nerve was imbedded. The heart presented eccentric hypertrophy in all parts, especially in the left ventricle. The muscular substance was pale and friable. The endocardium was thickened and opaque in some parts of the left ventricle. The tricuspid, mitral, and pulmonary valves were normal; the aortic valves were shriveled, thickened, and calcified at the base, so as to be manifestly incompetent; the size of the orifice was also diminished. The aorta was somewhat dilated, and presented atheromatous and calcareous degeneration. The coronary arteries were atheromatous and calcified, and their orifices narrowed. The liver was small and pale, and in the gall-bladder were two calculi. The spleen was enlarged and dense; the kidneys small and slightly granular, with a small calculus in the right. The alimentary canal was normal, but there were two inguinal and an umbilical herniæ.

THE SANITARY CONDITION OF THE ROMAN HOTELS.

THE *Times* and *Gazette* reproduces some accounts of the sanitary condition of the Roman hotels, which may be of interest to travelers and to physicians:—

The *Italian Times* Sanitary Commission is making steady progress with its inquiry into the sanitary condition of the hotels of Rome, though at one time it was threatened with serious opposition from a very unexpected quarter. A general meeting of the Italian Medical Society was summoned to discuss, among other subjects, "Measures to be taken in view of the arbitrary interference of certain foreign medical practitioners with the hygienic condition of the Roman hotels." This proposal appeared to be very absurd and uncalled for, for the hotel-keepers themselves welcomed this inquiry, and two of the most distinguished members of the Society, Drs. Manassei and Fioridespini, are members of the sanitary commission. However, in consequence, apparently, of a letter from Dr. Fioridespini, the proposed discussion was allowed to drop. But the *Popolo Romano* has published an article from an Italian physician, denying the right of foreign physicians to interfere with Roman sanitary questions, in which he tells a little story that shows how desirable it is that hotel-keepers in Rome should be supervised and educated in other matters besides questions of drainage, ventilation, and other structural defects. He says: "A short time since a Protestant clergyman attended a lady, one of his co-religionists, who died of typhoid fever in one of the principal hotels of Rome. The next day the same clergyman called on the Bishop of Gibraltar, who had just come to Rome, and had gone to lodge in the same hotel. To his great surprise he found him occupying the very room in which the lady had died of typhoid fever the day before." The *Italian Times* remarks: "The Italian physician apparently sees nothing disquieting or improper in this." English visitors to Rome will take a very different view of it from that of the Italian physician, and it is to be hoped the sanitary commission will "make a note of it." It is very satisfactory, meanwhile, to learn that the Quirinale, Coustanzi, Bristol, Europa, Molaro, Anglo-Americano, Parigi, Russie, and Victoria hotels have already been inspected, and that the proprietors have in all cases expressed their willingness to carry out the reforms suggested. We are glad to learn, also, from the *Italian Times* of June 4th, that the municipal council of Rome had just recently appointed a committee to examine and report upon the town drainage, especially with reference to the connection between the hotel drains and the general system of sewers.

THE SMALL-POX AND INOCULATION.

APROPOS of distempers, I am going to tell you a thing that will make you wish yourself here. The small-pox, so fatal and so general among us, is here entirely harmless by the invention of *ingrafting*, which is the term they give it. There is a set of old women who make it their business to perform the operation every autumn, in the month of September, when the great heat is abated. People send to one another to know if any of their family has a mind to have the small-pox; they make parties for this purpose, and

when they are met (commonly fifteen or sixteen together) the old woman comes with a nut-shell full of the matter of the best sort of small-pox, and asks what vein you please to have opened. She immediately rips open that you offer to her with a large needle (which gives you no more pain than a common scratch), and puts into the vein as much matter as can lie upon the head of her needle, and after that binds up the little wound with a hollow bit of shell, and in this manner opens four or five veins. The Grecians have commonly the superstition of opening one in the middle of the forehead, one in each arm, and one on the breast, to mark the sign of the cross; but this has a very ill effect, all these wounds leaving little scars, and is not done by those that are not superstitious, who choose to have them in the legs, or that part of the arm that is concealed. The children or young patients play together all the rest of the day, and are in perfect health to the eighth. Then the fever begins to seize them, and they keep their beds two days, very seldom three. They have very rarely above twenty or thirty in their faces, which never mark, and in eight days' time they are as well as before their illness. Where they are wounded there remain running sores during the distemper, which I don't doubt is a great relief to them. Every year thousands undergo this operation; and the French ambassador says pleasantly, that they take the small-pox here by way of diversion, as they take the waters in other countries. There is no example of any one that has died in it; and you may believe I am well satisfied of the safety of this experiment, since I intend to try it on my dear little son. I am patriot enough to take pains to bring this useful invention into fashion in England; and I should not fail to write to some of our doctors very particularly about it, if I knew any one of them that I thought had virtue enough to destroy such a considerable branch of their revenue for the good to mankind. But that distemper is too beneficial to them not to expose to all their resentment the hardy wight that should undertake to put an end to it. Perhaps, if I live to return, I may, however, have courage to war with them. Upon this occasion admire the heroism in the heart of your friend. — *Lady Mary Wortley Montagu.*

RUPTURE OF THE PLANTARIS MUSCLE.

In *The New York Medical Journal and Obstetrical Review* for July, 1881, Dr. A. B. Judson gives three cases in which he diagnosed this injury. He remarks that it is seldom found described in systematic works on surgery, although its occurrence is probably not very uncommon. Its most remarkable feature is the trivial nature, or almost entire absence, of an immediate cause. Persons are attacked while quietly walking in the street, stopping suddenly under the impression that they have been shot in the leg. Apart from oedymosis, which is met with in but a limited number of cases, the only objective signs are oedema and deep-seated inflammation, and these are by no means constant. If there is an obvious gap in the muscles, with an adjacent muscular tumor, the case is to be considered one of rupture of the muscles, the term *ruptured foot* being conveniently used to indicate those cases in which the exact lesion remains undetermined. The diagnosis depends on (1) the suddenness of the

attack; (2) the insignificance of the apparent cause; (3) the location of the trouble; (4) the pain, which is absent or slight, when the part is at rest, and produced or aggravated by those motions of the limb, active or passive, which disturb the muscles of the calf; and (5) the great disproportion between the objective and subjective symptoms. Recovery is always protracted, and is probably not much facilitated by treatment, which, however, should not be neglected, for the prognosis is sometimes unfavorable especially when the affected limb is the seat of deep varicose veins, or shows traces of former phlebitis. Local and general remedies should be directed toward the relief of pain. Repair of the injured structures should be promoted by preventing motion or disturbance of the part affected. The condition which seems best adapted to secure this object is that of enforced fixation with the knee moderately flexed and the ankle moderately extended. As recovery progresses, locomotion will be facilitated by a high-heeled shoe, which prevents the foot from being unduly flexed on the leg. Cases of this injury present opportunities for the exercise of judgment in the decision of the question of abandoning further rest and resorting to motion and exercise.

CHEMICAL EXAMINATION OF DRINKING-WATER.

REQUEST FOR SPECIMENS OF SUSPECTED WATER.

A REQUEST for specimens of suspected drinking-water appears in a late number of the *National Board of Health Bulletin*, a careful study of the chief methods in use for the chemical examination of potable water, so far as organic matter is concerned, having been undertaken by order of the National Board of Health. It is particularly requested of the correspondents of the board, of medical men throughout the country, and of others interested in sanitary matters, that any well-marked case of disease which may seem on medical grounds fairly attributable to organic impurities in drinking-water be promptly reported to Dr. J. W. Mallet, University of Virginia Post Office, Albemarle County, Virginia, with a few lines stating clearly the medical nature of the case, and the character of the evidence on which the water in question is suspected of having actually caused disease in persons who have used it.

It is further desired that a sample of each such water be forwarded for examination, *but not until notice has been received from Dr. Mallet that the analysts are ready to proceed with it*, since it is important that no useless delay should occur between the shipping of the sample and its investigation in the laboratory. In notifying any one who may be able to furnish specimens of suspected waters that may be forwarded, clear instructions will be sent as to the quantity of water required, and the mode of collecting, packing, and shipping it.

It is particularly desired that no case be presented on doubtful or vague evidence, since one important object of the inquiry demands that all such be rejected, and only those cases examined which involve the strongest grounds for believing that mischief has really been caused by organically foul drinking-water.

The cost of packages and transportation for samples will be borne by the Board of Health.

HAY-FEVER.

M. DE BUDBERG's remarks at a meeting of the Société Vaudoise de Médecine, republished in the *British Medical Journal*, would indicate that Americans monopolize neither the knowledge of the sufferings from hay-fever nor the want of knowledge of its causes and treatment. M. de Budberg stated, at the Société Vaudoise de Médecine, that hay-fever is prevalent in Switzerland, as much amongst the Swiss as amongst the English, and that its frequency seems to increase at the present time. The clinical description of this disease has been known since the time of Phœbus. Dr. Blackley has demonstrated the majority of the causes of it; but we have not yet found any certain method for its cure. The object of M. de Budberg's work is to draw the attention of his colleagues to a method of treatment discovered by Helmholtz, and employed successfully by M. de Budberg, but as yet but little known. The first case was observed by M. de Budberg in an Englishwoman, who had suffered from it for twenty years. The treatment employed consisted of nasal irrigations of solution of quinine, recommended by Helmholtz (1 part in 750 of water). These irrigations brought away masses of brownish mucus, in which

were found small round yellow corpuscles, of smaller dimensions than the blood corpuscles. It did not contain either vibrios or bacteria. After two or three douches, the patient was perfectly well. The attack was arrested from that time. A solution of chlorate of potash was employed, and no relapse occurred, although the patient frequently passed flowering meadows. Every time that she attempted to suspend the treatment, a relapse occurred, which, however, was promptly ameliorated by the use of the douche. M. de Budberg thinks that the yellow corpuscles found in the nasal mucus of this lady were pollen corpuscles. The nasal douche freed the mucous membrane from them; hence its curative effect. In cases in which the mucus contained bacteria, Helmholtz's solution of quinine would probably be indispensable. In all cases, it is necessary that the douche should be made most carefully, so as to entirely wash out the whole of the nasal mucous membrane. Dr. Blackley, in his excellent monograph, relates that he induced hay-fever in his own person by the introduction, on the nasal mucous membrane, of various kinds of pollen. He cites more than sixty different kinds of them,—as a rule, graminaceous pollens.

Deaths reported 4032 (no return from Cincinnati); 2426 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 1749, diarrhœal diseases 1229,

consumption 329, lung diseases 177, diphtheria and croup 163, scarlet fever 114, typhoid fever 42, measles 39, small-pox 38, malarial fevers 33, cerebro-spinal meningitis 30, whooping-cough 24, puerperal fever 16, erysipelas 12, typhus fever nine.

From *typhoid fever*, Chicago nine, Philadelphia and Pittsburgh six, Baltimore five, New York and Boston four, Providence two, Brooklyn, St. Louis, Charleston, Worcester, Cambridge, and Brookline one. From *measles*, New York 13, Baltimore nine, Pittsburgh seven, Brooklyn and Chicago three, Providence two, Milwaukee and New Bedford one. From *small-pox*, Philadelphia 16, Chicago 10, New York seven, Pittsburgh three, Brooklyn two. From *malarial fevers*, New Orleans nine, St. Louis eight, Chicago four, Brooklyn and New Haven three, District of Columbia and Pittsburgh two, Baltimore and Buffalo one. From *cerebro-spinal meningitis*, New York seven, Chicago six, St. Louis four, Pittsburgh three, Worcester, Lynn, and Pittsfield two, Philadelphia, Buffalo, Milwaukee, and Springfield one. From *whooping-cough*, New York seven, Chicago five, Brooklyn and St. Louis three, District of Columbia two, Philadelphia, Boston, Milwaukee, and Cambridge one. From *puerperal fever*, New York, Chicago, Boston, St. Louis, Baltimore, and Lowell two, Philadelphia, Pittsburgh, Milwaukee, and Gloucester one. From *erysipelas*, New York and Baltimore three, Philadelphia, Brooklyn, Chicago, Providence, Cambridge, and Taunton one. From *typhus fever*, New York nine.

Twelve cases of small-pox were reported in Brooklyn, 27 in Chicago, two in St. Louis, one in District of Columbia, one in Buffalo, 30 in Pittsburgh, four in New Bedford, two in Westfield; diphtheria 17, scarlet fever five, in Boston; scarlet fever 16, diphtheria eight, in Milwaukee.

In 10 cities and towns of Massachusetts, with a population of 1,035,883 (population of the State 1,783,086), the total death-rate for the week was 18.02, against 17.00 and 15.64 for the previous two weeks.

For the week ending June 18th in 149 German cities and

towns, with an estimated population of 7,896,848, the death-rate was 26.7. Deaths reported 4058; 2003 under five: pulmonary consumption 574, acute diseases of the respiratory organs 309, diarrheal diseases 242, diphtheria and croup 140, scarlet fever 85, typhoid fever 49, measles and röteln 48, whooping-cough 31, puerperal fever 24, small-pox (Königsberg, Ratisbon two, Munich, Berlin, Charlottenburg, Kottbus, Hamburg, Aachen) nine, typhus fever (Königsberg, Thorn, Bromberg) three. The death-rates ranged from 15.1 in Potsdam to 38.8 in Chemnitz; Königsberg 30.7; Breslau 29.2; Munich 33.2; Dresden 22.4; Berlin 30.8; Leipzig 22.3; Hamburg 24.7; Hannover 22.4; Bremen 31.1; Cologne 28; Frankfurt 20.1; Strasburg 30.4.

For the week ending June 25th, in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 18.5. Deaths reported 2700: acute diseases of the respiratory organs (London) 210, small-pox (London 88) 93, measles 91, whooping-cough 88, diarrhoea 73, scarlet fever 50, diphtheria 23, fever 23. The death-rates ranged from 9.7 in Plymouth to 23 in Liverpool; Bristol 17.4; Birmingham 18; Leeds 18; Manchester 18.5; London 19.1; Sheffield 20.6. In Edinburgh 17.4; Glasgow 18.7; Dublin 24.5.

In the 21 chief towns of Switzerland, for the week ending June 25th, population 479,934, there were 23 deaths from diarrheal diseases, acute diseases of the respiratory organs 20, measles 14, typhoid fever 13, diphtheria and croup seven, whooping-cough one, puerperal fever one. The death-rates were: Geneva 17.5; Zurich 26.4; Basle 31; Berne 35.1; St. Imier 29; Herisau 14.

The meteorological record for the week in Boston was as follows:—

CONTAGIOUS AND NON-CONTAGIOUS YELLOW FEVER.

BY THOMAS H. BUCKLER, M. D., OF BALTIMORE.

WHEN, in the summer of 1855, half the people of Norfolk died or disappeared from epidemic yellow fever, which is spread, carried, and communicated through contact of germs with morbid atmospheres, and not by contagion or infection, from the sick to the well, daily indirect intercourse was kept up with Baltimore.

I wrote out at the time the conditions on which this intercourse might be safely maintained.

The Bay Line of boats from Baltimore exchanged, every morning in Hampton Roads, near Fortress Monroe, and later in the season at a more remote point opposite the Ripraps, passengers coming and going by the steamer Coffee from and to Norfolk.

No restraint whatever was put on passengers going either way, and the result was that a large number sickened after reaching Baltimore, and of these, about seventeen, of whom special notice was taken, died, some of them in crowded and questionable localities, without in a single instance communicating the disease to any one.

Mr. T. died at —, when the hotel was unusually crowded, after an illness of five days, his room having, in a very marked degree, the peculiar odor of the disease.

A lieutenant of the navy died at a crowded boarding-house on the southwest corner of Charles and Fayette Streets.

A deck hand died on Fell's Point, in one of those human pig-sties described in the report of Dr. Chancellor.

All of these had been attacked within a few hours after their arrival from Norfolk, but in no instance was the disease communicated to a single inhabitant of Baltimore.

If a quart of air from about the Norfolk wharves had been carried in a closed box, and let loose near the Basin and docks, or over one of the slaughter-house drains running through the city, it might, by acting through catalysis on air prepared to receive it, have converted the whole surrounding atmosphere into its kind, and have produced thereby an extended epidemic of non-contagious yellow fever.

The Norfolk visitation was the true epidemic, non-infectious fever, which appears, as far as its past history shows, in cycles, at intervals of about seventeen years, and carries in its march a fearful mortality, far beyond that of any other known malady of modern times.

Propagated solely by the intermingling of morbid atmospheres or waters, it is carried from one seaport to another by taking, in sea-going vessels, the infected air or water from a port in which the disease exists, and thereby introducing the catalytic poison or germ into an atmosphere charged with the products of zymotic ferment, and where, like an air-plant, it finds elements on which to feed and propagate its lethal kind.

True epidemic yellow fever, clearly not contagious or infectious in the slightest degree, has, unhappily, been too often confounded with a less fatal, but contagious and infectious malady, which is also character-

ized by the phenomenon of yellowness, even more marked and constant than that of true typhus icterodes, in which latter the saffron color does not, in many cases, appear until after death.

Infectious yellow fever of an internal hemorrhagic character occurred amongst the free negro population of Baltimore from the first of April to the middle of July, 1846, and an epidemic of a like kind, also affecting negroes, happened in Philadelphia some years before. The cases came from every ward in Baltimore, and were so numerous that the spinning and other work-rooms had, for want of sufficient hospital accommodation, to be converted into fever wards.

I saw but two mild cases in whites, one an Irish girl, and the other the daughter of a prominent citizen. Several nurses, as well as my memory serves me, six in all, sickened, and of these two died. None but nurses took the disease, showing that its poison only had effect at short distances.

The whites of the eyes were deeply jaundiced in every case, and after death all the internal tissues usually white were found saffron-colored. Wherever loose cellular tissue existed, clots of blood, of greater or less size, were found extravasated. In the cellular plot-work of the lungs I observed in every case, out of dozens examined, masses of coagulated blood, from the size of a millet-seed to that of a pullet's egg, and in numbers too numerous to be counted, even in a single lobe. Blood was also effused into the connective tissue, between the mucous and muscular tunics of the stomach and intestines, in spots differing in color, but as well marked in shape and size as those on the stems and branches of the conium maculatum in its green state, but in no single case was there black vomit or other sign of decomposed blood passed from the stomach or bowels.

It appears, therefore, that while in this form of infectious yellow fever blood is only effused underneath, in the epidemic, non-infectious, true disease, of more common occurrence, it exudes through the mucous membrane into the stomach and intestines.

The disease carried to the alms-house spared neither age nor sex. Infants at the breast, old men and women, and those of intermediate ages suffered alike, the attacks increasing in mortality as the ages of men exceeded forty-five, but in women the adverse effect of age was less apparent.

The two whites, both women under twenty, and both of whom recovered, had a slight exanthematous efflorescence over the chest, upper part of back, and shoulders, but very sparsely scattered on loins and limbs. The same measly erythema happening in blacks would be hid from view by pigmentum nigrum.

In Stirling Street, occupied on both sides by Irish, German, and negro families, living in separate small houses, while all the negro dwellings were closed, every soul in them having been attacked and sent to the alms-house hospitals, I could not find, on diligent personal inquiry, that a single white was or had been sick with the peculiar malady. The Hanseatic tenement-house, occupied by seven negro families, and remote from Stirling Street, was also closed, all its inmates having been attacked and sent by city police to the alms-house.

The first cases of this disease having been brought from Ell Alley, back of the public stores, and near Gay Street wharf, gave rise to fear that the disease might have been imported, but this apprehension was

soon allayed by new cases dropping in from other parts of the town remote alike from each other and from Ell Alley.

It would appear, therefore, that a differential diagnosis ought in all cases to be carefully and clearly drawn between fever like the one just described, for which the isolation of individuals laboring under it, rarely required, might still be justified, and true epidemic yellow fever, typhus icterodes of systematic writers, in regard to the prevention of which extreme vigilance is so often required, and where in every case it is for the safety of individuals and communities so absolutely necessary to quarantine the vessels containing yellow fever germs or yeast in the air of closed compartments or in bilge-water, but where passengers and sailors may, without risk to a human being, be allowed perfect liberty to go beyond the ship or infected region when and where they please.

With this understanding the horrors of quarantine, growing out of the idea that restraint to individuals is necessary, would in the very large majority of instances be entirely avoided.

The evils and terrors connected with quarantine depend on the needless confinement of individuals, and not on the absolutely indispensable detention of vessels, and as a very general rule dry cargoes transhipped by wholesome vessels may be allowed to enter the port or ports to which they are consigned.

Nothing could illustrate more clearly the foregoing view, or furnish stronger proof of its correctness, than the following cases, and the circumstances surrounding them.

During the summer of 1855, when yellow fever devastated Norfolk, a family composed of four members, and four servants, went from Baltimore to Old Point Comfort, to spend the season, as had been their custom, in a cottage close to the water's edge, on Hampton Roads, and not twenty yards from the outer wall of Fortress Monroe.

They apprehended no danger, and having been informed by the officers of the fort that a strict sanitary cordon was, and would continue to be, enforced against Norfolk and Hampton, where fever also existed, they felt safer, with their ideas and opinions in regard to infection, than they could possibly be in Baltimore, whither, without restrictions of any sort, a number of people came every day from Norfolk.

The commander of the fort, believing that safety depended not entirely on distance, but rather on avoiding communication with any person or contact with anything coming from the infected region, would not allow the steamer *Coffee*, from Norfolk, to stop, as she had been accustomed to do, at the Old Point Pier for the daily receipt and dispatch of letters, packages, stores, etc., brought no longer direct from Norfolk, but only after having exchanged passengers and mails with the Baltimore boat lying in the roadstead.

For the convenience and dispatch of sending a row-boat from shore for letters, the *Coffee* was ordered to come to, and lie off in the open roads, at a point about a hundred yards from an extemporized platform on shore, to which ear boats could be moored, much nearer the fortress than the pier is, and directly opposite the cottage occupied by the Baltimore family.

From the open windows of a room looking on the water, and about forty yards distant from the point of transhipment, a mother and daughter, aged respectively about sixty and twenty years, watched for several days

the pitching of post matter and packages from the steamer to the row-boat and back.

As a matter of course, when the *Coffee* stopped, closed compartments containing the bad air shut up in them at Norfolk being opened to get things out, whiffs of it were sent by the breeze blowing in the direction of the cottage, to be breathed by these ladies, who were both seized the same morning with a slight chill ushering in yellow fever.

This looks as if the poison, whatever it may be, causing this disease acts catalytically, not only on atmospheres primed with the products of zymotic ferment, producing its like, but also directly on human blood, giving rise to ferment in it, and all the fearful array of phenomena characterizing yellow fever. Surely there is no other disease for the stamping out of which preventive medicine has so important a part to play.

The degrees of modern civilization in different countries may be measured better by the relative advancement each, compared with the others, has made in sanitary science, and its practical applications in architecture, engineering, and the arts generally, as applied to social life, than by any other scale offered by individuals or committees for the judgment of their peers.

To resume: both ladies having spent several consecutive seasons at this cottage, and being much beloved by the families of the garrison and people surrounding it, were from the moment of seizure under the tender and assiduous care of the physicians, officers, and women of the place: all, regardless of rest or personal convenience of every kind, did much and were prepared to do more, had time and opportunity afforded them the power. All the means and remedies so generally unavailing in this disease were used. When I saw them on the fourth day the mother was laboring under profound coma with stertor, and died the next morning. The daughter had dejections of dark decomposed blood from both stomach and bowels, and survived her mother only a few hours. It should here be noted that while all inside of the fortifications, and people outside of them, were exposed to the air immediately surrounding these unfortunates, before and after death, yet these two were the only cases which happened during that entire season at Old Point Comfort, or in its immediate neighborhood.

Was this disease communicable from the individual laboring under it, or would the same immunity have been enjoyed, had variola, rubella, or any other well-known infectious or contagious disease been introduced amongst a like number of unprotected men, women, and children?

A strict military cordon having been kept up, and nobody from Norfolk or Hampton having been allowed to land or come near the fort, how is it possible that these two ladies, the only persons attacked at Old Point, could have contracted the fever in any other way than by inhaling the whiffs of yellow fever air, let out from compartments which, having been closed in Norfolk, were, when the *Coffee* stopped, opened within ten rods of its victims?

These two cases having been thus contracted, while hundreds of refugees went directly from Norfolk to Baltimore, where many died without communicating the disease to a single human being, furnish irrefutable and conclusive proof that the people of Norfolk also contracted the fever from breathing the previously infected air of the place, and not from coming in contact with, or in proximity to, any one laboring under the

disease; that the air got sick first, by having had introduced into it yellow fever yeast, by a vessel from the West Indies; that the sufferers from it got ill from breathing the air on which the fever germ, poison, or yeast had already exerted its power of catalysis; and that additional strata of air were leavened successively is proven by the gradual enlargement of the disease-producing area, from day to day, the zone extending step by step, until it reached, at the close of the epidemic, a distance of five miles in every direction around Norfolk.

Excluding then the idea that this disease was propagated by either contagion or infection, we are forced to the conviction that the introduction into and spread of yellow fever amongst a community or family is due solely to the catalyzing elements contained in imported air or water, and that favored by a nutritive atmosphere charged with the products of zymotic or pestilential ferment, they synthetically blend and breed their like.

But sea-going vessels are not the only vehicles by which air impregnated with yellow fever yeast is carried from one community, plantation, or family to another.

The closed compartments of an express wagon, or of a railway post or baggage car, having been shut up in a fever-stricken town, and opened at the first relay, ten, twenty, or fifty miles off, may let loose the destroying angels that will, before a day has passed, produce legions of them, and yellow fever as a consequence.

An unseen enemy, of all others, excites always the greatest terror, and as the demon, yellow fever poison, can only, like the ghost of Hamlet's father, take psychologically the form of spectral hallucinations, or the more real shape of some unfortunate tramp or wretched wayfarer, the unreasoning country people having now imps, both actual and imaginary, to deal with, and being inspired by old Satan, and fear, the most vehement and brutal of all emotions, get out their shot-guns to warn him off or shoot him, if he comes in tangible shape, when the real enemy flanks them, by taking passage in the closed compartments of an express wagon or train to be let out in their rear, at some cottage, plantation, or farm-house, there to engender with air already polluted, and breed yellow fever.

Was the fever at Memphis true, imported, non-contagious typhus icterodes, or was it local, domestic, and self-originating? And did it resemble in other respects the yellow fever which was so fatal amongst the free blacks of Baltimore in 1816?

I incline to the opinion that there must have been at least a faint likeness, since true imported fever rarely happens, epidemically, two consecutive seasons in the same place.

In 1855 Norfolk lost half her population, but in 1856 she was entirely free from fever.

No doubt the eggs were there, producing other forms of zymotic disease, but to breed yellow fever, and leaven the loaf of bad air up to the epidemic standard, an importation of fresh yeast from the West Indies would have been required.

—Heschl, the successor of Rokitsky, as professor of pathological anatomy in the Vienna Medical School, was born in 1821, and took his degree in 1849. He was Rokitsky's assistant for four years, and afterwards was successively professor at Olmütz, Cracow, and Gratz. He was a good teacher. His *Compendium of Pathological Anatomy* was published in 1855.

THE INOCULABILITY OF TUBERCULOSIS.¹

BY WILLIAM F. WHESEY, M. D.

IN the paper this evening it is proposed to give a brief summary and criticism of the principal experiments which have been made with the view of solving what must be considered one of the most important questions of the day, namely, the inoculability of tuberculosis, a question not only of great theoretical interest but one of which the practical importance cannot be over-estimated, and the right solution of which, it is to be hoped, may give some indications for the prevention of this dreaded disease.

The possibility of the infection of one person from another has frequently been urged, and the cases of persons who have died from chronic lung diseases after long and faithful care of phthisical patients have been brought forward in support of this idea; but against this it has been argued that these were merely cases of coincidence, not to be wondered at, considering the great number of persons that die from such diseases, roughly estimated at one fifth of all deaths; and furthermore, if there was any connection between the two, it was merely that the second person had become debilitated by the long care, and thus was in a condition favorable for the development of the disease which was perhaps already there, through hereditary transmission.

The honor of having first attempted to advance the knowledge of the tuberculous processes by direct experiment is generally conceded to Villemain, who, in 1865, presented his first communication to the Academy of Sciences in Paris. Since then, the subject has been investigated from various points of view by the different experimenters, but all the experiments fall naturally into three classes, according to the way in which the tuberculous substance has been introduced into the economy of the animal; and a clearer understanding of the matter can be reached if each class is followed out separately, rather than if the simple chronological order of the whole is adhered to.

These three ways are, first, by direct inoculation of tuberculous material; second, by its introduction as food into the alimentary canal; and lastly, by allowing atomized particles to be inhaled.

The original experiments of Villemain² consisted in the direct inoculation of material which was taken from the lungs of persons who were said to have died from tuberculosis. The seat generally chosen for inoculation was behind the ear, and in some cases a seton impregnated with the material was allowed to remain in the neck. In all of the animals thus operated upon, tubercles were found not only in the lungs, but also in other organs. In 1866 he repeated his experiments, and obtained the same result. He also inoculated a rabbit from a cow, and from the first a second rabbit. In this manner he succeeded in inoculating guinea-pigs, but failed with dogs and cats. Tubercles were found in the lungs of the animals experimented upon after from ten to twenty days, and in the other organs in the fourth month. These experiments of Villemain aroused great interest, and were immediately repeated by a number of other observers.

Vogel³ made like experiments on various animals, a

³ Vogel. *Deutsches Archiv für klinische Medicin*, 2 Bd., s. 364, 1866.

eat, a cow, and a colt, but with entirely negative results.

Herard and Cornil¹ recorded the entire success of their inoculation of two rabbits with true tuberculous matter, while the results were negative when inflammatory products were used.

Hoffmann² was enabled to produce milary tuberculosis in two rabbits after inoculation with cheesy masses.

Genodet³ gave a brief notice of inoculation with softened tuberculous masses, and found, when the animal was killed, five months later, a mass of cheesy and partially softened glands in the mesentery.

In 1867 Lebert and Weiss⁴ published an account of forty-four experiments, which were divided into groups according to the nature of the substance and the way in which it was inoculated. The first series consisted of eleven experiments on rabbits and guinea-pigs, and was by direct inoculation. In the second series pus was injected into the veins of two dogs. Eight animals formed the third series, and these were injected subcutaneously with the contents of phthisical cavities and sputa from persons suffering from chronic lung diseases. All the animals in these series died shortly after inoculation. Then came a series of eleven experiments in which lymph glands, sarcomatous and cancerous masses were used, and finally another series of eleven, in which charcoal or quicksilver was injected into the veins. In the lungs of many of these animals, in whatever way they were treated, there were found grayish or cheesy disseminated nodules, which were like tubercles in their histological structure, and from their having been produced under so many different circumstances, they were looked upon by the authors as due to inflammatory origin, and they were thus led to consider tubercle as the result of simple inflammatory process, and deny to it any specific character.

Waldberg⁵ published a series of experiments in 1867, in which he arrived at the same conclusions as Lebert and Weiss.

Petroff⁶ however, reported one case in which, after the injection of tuberculous material into the pleural cavity of a rabbit, there was found what he considered as true tubercles at the end of twenty days.

Langhans⁷ comes next, who made a step forward in that he chose the conjunctiva bulbi as a point for inoculation in order to better watch the sequence of events. The result was that after a certain period of incubation there appeared a number of small, discrete, white spots, entirely different in appearance from what was produced if simple masses of inflammatory detritus were used for the inoculation. Secondary nodules were found in some of the internal organs, but as these were often found to be intimately connected with parasites, he considered that the previous experimenters had not been careful enough in this regard, and that the subject could not be considered as definitely settled, although he himself believed in the specific nature of the affection.

Klebs and Valentin⁸ introduced tuberculous masses into the peritoneal cavity of animals. In three cases, in which, according to them, true tuberculous matter was used, there followed a tubercular peritonitis and then a general infection. In nineteen cases in which various other substances were introduced negative results only were obtained.

Cohnheim and Frankel⁹ in like manner obtained tubercles after placing pieces of cheesy material in the peritoneal cavity of guinea-pigs. Then particles from bodies which were not tuberculous were found to work equally well, and finally pieces of indifferent substances, such as paper, rubber, etc., gave rise, apparently, to the same products. The results of these experiments were interpreted at that time as supporting Buhl's theory that the origin of tuberculosis was to be found in some local cheesy deposit, which in these cases was formed about the material used. Later Cohnheim was led to believe that these results were from some accidental inoculation from an unknown source, as both he and Frankel were unable to repeat these experiments successfully in other places.

Chauveau¹⁰ records success after the direct injection into the vessels, and also from subcutaneous injection, of tuberculous material.

In 1873 Bollinger¹¹ obtained one positive result among eight animals, using cats, dogs, and goats for his experiments.

From this time the attention of experimenters was turned in other directions, and it was not until 1877 that any advance was made in the way of direct inoculation. In that year was published Cohnheim's¹² Hand-Book of General Pathology, in which he gives an account of some experiments in which he chose the anterior chamber of the eye as the seat of inoculation. A piece of freshly extirpated scrofulous lymph gland was brought into the anterior chamber of the eye of an Albino rabbit by means of a small linear cut through the cornea on one side. After a few days the opacity of the cornea and the aqueous caused by the operation cleared up, and the inoculated piece was seen lying clearly defined against the lens. Thus affairs remained for weeks, the only change noticed being that the piece became a little smaller. Suddenly at the end of from twenty to thirty days the scene changed; there appeared in the tissue of the iris a number of small, transparent, grayish nodules, which projected a little into the anterior chamber of the eye, and between which the iris was intensely and diffusely reddened. In the following days the number of nodules increased, while some of the earlier ones reached a millimetre in diameter. From this time the appearances remained stationary for several weeks in some of the cases. In others there appeared a severe keratitis, and the eye was lost with a general panophthalmitis. In these cases there was no cheesy focus formed about the inoculated mass, but the eruption of tubercle followed simply after a stage of incubation.

These experiments of Cohnheim have been repeated by Baumgartner,¹³ who at first was unsuccessful, but found that his ill-luck lay in the fact that the material which he employed was not perfectly fresh. In order

to obtain this he used the lungs of cattle which were killed on account of tuberculosis (the so-called pearly distemper), and brought a small quantity of this in a state of fine division into the anterior chamber of the eye. After fourteen days a true tuberculosis of the iris developed, followed in the course of three to four months by a general tuberculosis of the lungs, liver, kidneys, etc., accompanied by symptoms of general marasmus. From these animals others could be inoculated, and so on through several generations. If the eye was enucleated before the time for the appearance of the general symptoms the animal's life could be saved. Experiments were also made by introducing various other substances, but the result was merely a purulent inflammation, which was never followed by a general tuberculosis. From the necessity of finely dividing the tuberculous masses, Baumgartner thinks that the virus must be contained in the state of fine molecular division within them, and considers the possibility of some form of micrococcus being connected with it.

Such are the chief experiments which have been made with the end in view of the direct inoculation of tuberculosis; there are several other questions which have been incidentally touched upon which will be considered later, as they are also common to the two other classes of experiments.

The class of experiments which will be next considered is that in which the attempt has been made to produce infection by introducing tuberculous substance into the alimentary canal.

The first who experimented in this direction was Gerlach,¹ at that time director of the Royal Veterinary School in Hanover, and the results were published in 1869. He obtained positive results in five out of six animals—two rabbits, two swine, a lamb, and a calf—that were fed with the milk of a tuberculous cow (pearly distemper). The length of time which the animals lived after the commencement of the feeding was from forty-two days to three months.

Klebs² published a few experiments in which he used the milk from tuberculous cows for feeding guinea-pigs. In four out of five animals there were found cheesy masses, which were held by the author to be of tuberculous origin, in the mesenteric glands and liver. In two cases milk was given after boiling, and these were also found to be infected in like manner. The case of a dog is also given, which died with all the appearances of tuberculosis after he had accidentally taken for a long time the milk of a tuberculous cow. These experiments of Klebs do not seem to have been conducted with sufficient care, in that there is no record of any control having been kept on the experiments by feeding a like number of animals on milk which did not come from tuberculous cows, but otherwise leaving them under the same conditions.

In 1872 Bollinger³ made experiments by feeding eleven animals with masses from the lungs of tuberculous cattle. In the cases of four dogs and one lamb the results were negative or doubtful. In the case of five goats the result was a positive one, while in one animal, which was used to control the experiments, and which was fed on cheesy pus from the liver of a pig, the result was negative. As a conclusion from

this he formulates that feeding with fresh tuberculous masses from the lungs of cattle produces no tuberculosis in the carnivora, while the feeding of the herbivora with cheesy and fresh tuberculous masses produces a wide-spread tuberculous infection, which finds its anatomical expression in intestinal ulceration, hyperplasia of the intestinal follicles, marked swelling and cheesy degeneration of the retroperitoneal glands, and often in tuberculous eruption in the peritoneum, the liver, and lungs.

Against these experiments are to be ranged those of Colin and Friedlander,⁴ the former of whom denied entirely the infectiousness of the pearly masses from the cow, and the latter thought that the miliary bodies which were found in the course of his experiments failed to have all the histological characteristics of tubercles, and considered the whole process as one of chronic pyæmia.

Positive results were obtained, on the other hand, in 1877 by Orth,⁵ who employed rabbits, and introduced the substance by means of blunt forceps into the upper part of the pharynx, in one case the animal eating the tuberculous masses voluntarily. The experiments were so arranged that five animals were placed in a cage under the same circumstances, and four cages were used, in all twenty animals. In each set of five animals one received fresh masses from tuberculous cattle, one the same after it had been boiled for a few minutes, the third and fourth received raw and boiled cheesy masses from human subjects, while the fifth animal remained as control. In all four cages the animals which received the raw masses from cattle were found to be infected, as were also three out of the four which received the cooked; while those which had received the raw and boiled cheesy masses from the human subject, as well as the controlling animals, remained healthy. The lymph glands of the neck were found affected in all of the infected animals, having cheesy centres, and at the periphery presenting the characteristic appearance, both to the unaided eye and by the microscope, of tubercles. In the stomach of one and in the intestinal tract of the greater number of the affected animals were found ulcerations, in which were nodules resembling tubercles in their histological structure. In the animals which showed the slightest changes in the seat of inoculation there were found in the lungs discrete miliary nodules, which in the more extensively affected animals had formed solid masses, often with cheesy degeneration and cavities. These were subjected to a careful histological investigation under the direction of Orth, and were found in their structure, in the presence of giant cells, and in the absence of vessels, to correspond fully with the tubercles found in human lungs. In the liver, kidneys, pleura, and omentum, were also found similar tuberculous nodules. By a comparison of his results it was found that there appeared to be a certain time for incubation required before the gross appearances of tuberculosis were seen, which was about two months. Orth suggests that the infection is connected with bacteria, but was unable to demonstrate any.

Virchow⁶ began in 1876 a series of experiments, the results of which were published about a year ago. First of all he is inclined to doubt the anatomical iden-

tity of the pearly distemper of cattle and tuberculous of man, on the ground that it has a tendency to calcification rather than to cheesy degeneration, forms enormous pedunculated masses hanging free in the serous cavities, and without the tendency to ulcerative destruction. His experiments were made principally with the end in view of proving whether the milk of animals affected with the pearly distemper could reproduce the disease when fed to other animals. His first objection to the experiments which have been performed up to this time is that the various chronic inflammatory processes which occur spontaneously in animals are not sufficiently well known even to veterinary specialists, and in pigs, which he used in considerable numbers, from their alliance to man through their omnivorous habits, serofulous glands occur so frequently, and their detection during life is a matter of so great difficulty, that results founded upon their presence must be accepted with great caution. The possibility of coincidence was also well illustrated by one case in which several animals were found to be tuberculous after having taken the milk for some time from a cow which was diagnosed during life as affected with the pearly distemper, but whose lungs were found filled with echinococci cysts at the autopsy. The only result which he thinks is justified from his experiments is that more animals were found to be tuberculous among a certain number which had been fed upon the "pearly" milk than among the same number which had been fed upon healthy milk. Further and varied experiments must be tried before the matter can be decided.

The last class to be considered is that in which the substance is brought directly into the lungs, either by direct injection through the trachea, or by allowing the animal to remain for a certain time in an atmosphere impregnated with fine particles of the substance by means of an atomizer. The first experiments of this kind were made by Lipp¹ by direct injection through the trachea. His original I have not been able to see, but from the citations of succeeding authors judge that his results were to him, at least, positive. At about the same time Tappeiner² published the account of his experiments, which were made upon eleven dogs, and were arranged in the following manner: A dog was placed in a cage about one cubic metre in dimension. About a tablespoonful of sputa from persons affected with tuberculous cavities was then diluted with water to 300 to 500 cc. of water, and then thrown into the cage by means of a large atomizer. The experiments were varied in the amount of fluid and the length of time to which the dogs were submitted to the inhalation. In general they inhaled once or twice daily for a period extending over three to four weeks. In all but one of these cases tubercles were found in the lungs, and in the greater portion of the animals in the other organs also, after the third week from the time of the commencement of the inhalation. A curious clinical phenomenon, and one which should have weight in determining whether this eruption of miliary granules is identical with that in the miliary tuberculosis of man, is the fact that the dogs, instead of becoming emaciated, held their weight, and in some cases even increased.

As arriving at a different result by employing the

same methods is next to be considered the work of Schottelius.³ He tracheotomized various kinds of animals, sixteen in all, and blew through the canula by means of a rubber balloon various substances reduced to the state of a fine powder. These were of two classes, — organic substances capable of undergoing decomposition, feces, and pus from a psoas abscess, and inorganic substances, lamp-black, cinabar, and precipitated Berlin blue. The result of the inhalation of the inorganic substances was simply to produce slight chronic interstitial changes which were without marked effect on the general economy of the animal, while on the other hand if the organic substances were used there followed an inflammation, with a tendency to destruction of the lung parenchyma, accompanied by circumscribed foci of inflammation in the lymph vessels and notable changes in the wall of the bronchi. In order to control these experiments he arranged a cage and atomizer after the manner of Tappeiner, and had four dogs inhale daily for several weeks (1) the sputa of phthisical persons, (2) sputa from patients who were not tuberculous, (3) finely rubbed up Limburger cheese, and (4) fresh calf's brain. In all of these there were found similar miliary granulations in the lungs, which, whether they were to be considered as tubercles or not, prove to him that the conclusions of the former experimenters, Lipp¹ and Tappeiner, in assigning a specific character to tuberculosis, were not justified in this regard, since a similar state of affairs could be produced by such different means. Whether or not this point can be proved by later experiments it will in no way detract from the value of Schottelius's work, of which the brief limits of this paper will not allow room for a sufficient abstract, but which should be carefully read by all experimenters in this field.

During the last year Tappeiner⁴ has repeated his experiments again, in the Pathological Institute in Berlin, with positive results. In the case where phthisical sputa was used tubercles were found in four cases, the anatomical diagnosis resting upon the authority of Drs. Israel, Grwitz, Friedlander, and Professor Virchow. In the cases where pus from ulcerating serofulous glands was used, and sputa from chronic bronchitis, the results were negative. In regard to the work of Schottelius he claims that he erred in injecting and allowing such large doses to be inhaled, for in this manner the substances all acted simply as foreign or putrid bodies; while in his own experiments the amount inhaled at one time was so small that no local reaction was produced at the time, and it was only after a period of incubation that the eruption of miliary granulations took place, which shows the specific character of the disease.

The same conclusions are supported by the observations of Bertheau,⁵ which were made on dogs and rabbits, and in which he was careful to use other animals for control.

In addition to these a book has been published within the last year by Professor Max Schuller⁶ on the experimental production of tuberculous and serofulous diseases of the joints. He used the method of injecting tuberculous material into the lungs, and finds that after the general infection of the animal the process

¹ Schottelius. Virchow's Archiv, Bd. 73, s. 524.

³ Bertheau. Deutsch. Archiv für pr. Med., Bd. 26, s. 523.

⁴ Schuller. Experiment. Untersuchungen über d. Entstehung der rheumat. u. tubercul. Gelenkleiden.

⁵ Virchow's Archiv, Bd. 74, s. 393.

also localizes itself in a joint which may have been contused at the same time. The work is altogether too extensive to be gone into in detail, but his conclusions need to be confirmed by other observers, as septic and pyæmic processes are by no means excluded from his results. He has been aided by Reinstadler,¹ who has endeavored to cultivate the germs found in the tuberculous masses, and claims to have produced tuberculous by the intra-pulmonary injection of the results of these injections, their breeding.

CONCLUSION.

The conclusion which we are obliged to draw is that there is still uncertainty in the matter, considering that all the experimenters are not agreed in the results which they have reached. It is true that almost all have obtained an eruption of miliary bodies after injections, inhalation, and feeding with what was presumably tuberculous material; but the interpretation as to what these really were has differed with the experimenter, the one side holding that they were simple inflammatory products, the other that they were true tubercles. Then, again, allowing that they are tubercles, is the tubercle the result of a specific process, or is it simply one of the expressions of inflammation that may arise as the result of various irritants?

Taken by themselves the latest experiments of Cohnheim, Tappeiner, and Orth, who are perhaps the more worthy of belief in that they have been able to avoid some of the errors of the earlier investigators, seem to point clearly to the fact that tuberculous is an acute infectious disease, and Klebs has proposed for the nodules of syphilis, glanders, and tuberculosis the name of infectious tumors rather than that of granulation tumors, under which name they have been associated together by Virchow on account of their histological character; and Cohnheim has gone so far as to propose as a test for tubercle, not its histological structure, not its peculiar arrangement of cells of varying size, without vessels and with a tendency to cheesy degeneration, but its capability of inoculation.

But whatever may be the opinion of individuals, the mass of scientists have a right to demand more and clear proof, and it may confidently be expected, with the light thrown upon the subject already, that within the next five or ten years sufficient proof will be furnished to prove or disprove the question.

So much for the scientific aspect of the question; and while we are waiting for this solution of the subject there are hints thrown out in these experiments which may serve as guides in practice. It is with this in view that I have brought the experiments before you according to the ways in which the substance has been introduced into the body, and these, as you remember, are by direct inoculation, as food, and by inhalation. The first need not detain us. As to the second, there is little danger of directly eating tubercle it is true, but there is a disease of cattle which has only very slight anatomical differences from, and is believed by the greater part of observers to be identical with, human tuberculous; and if the results obtained by certain experimenters are verified it does not require a very acute mind to see the danger of infection that is run by all of us, but especially by children. Our present state of knowledge does not warrant us in getting up a popular excitement or scare on the

subject, but it behooves us as physicians to thoroughly investigate the source of supply when we place a patient upon milk diet, and above all when we wish that a weakly child should have the milk of one cow be sure that that cow is healthy.

The other possibility of infection lies in the atmosphere in the neighborhood of tuberculous patients becoming charged with particles by their expirations and coughing. And knowing how utterly powerless we are to cure the disease when once established, we should impress upon those in close attendance upon the sick person the necessity of holding their breath when duty or affection brings them into close proximity to the face of the sufferer, especially during the act of coughing. Also the great desirability of keeping a strong solution of carbolic acid or thymol in the vessels used for the reception of sputa from such patients, especially in hospitals, where the patients had perhaps best be kept in a separate ward.

A CASE OF ABDOMINAL ABSCESS IN RIGHT ILIAC AND INGUINAL REGION.²

BY E. W. CUSHING, M. D.

G. L., male, aged twenty-two, quadroon, slight, fair, of rather delicate health, but usually well, was employed in a publishing establishment.

As part of his duty he daily carried a bag of silver coin up a long flight of stairs; he never had any difficulty in doing this, but on January 22, 1881, having carried a weight rather heavier than usual, some forty pounds, he was seized with violent pain in lower abdominal region, so that he went home and went to bed, supposing that he had "strained something." For five days he kept his bed, having fever, abdominal pain, and difficulty in urinating, with much pain in region of bladder.

On the sixth day he went to work again, but could do nothing, and had to be sent home in a carriage.

On the seventh day I was called and found him somewhat feverish; the face anxious and drawn; able to walk with great difficulty and only by moving slowly, bent forward, and assisting himself by supporting the right thigh with both hands. The pain was referred to the right iliac region, and was especially severe after urinating. The urine was thick, muddy, having an abundant deposit of urates. Rest and warm applications with an infusion of triticum repens was advised.

The condition remained about the same until February 6th, the fifteenth day, when there was more decided fever, great pain, and a tumor formed in the right iliac fossa which became more evident on the next day, when Dr. Ellis saw the case in consultation and concurred in the opinion that suppuration was going on, and that the case was very serious.

On February 9th, the seventeenth day, Dr. Beach was called in consultation, particularly with regard to the question of attempting to open the mass in the right iliac fossa supposed to contain an abscess.

Dullness was now found in the right iliac fossa, five inches in length, parallel to Poupart's ligament, and two inches in width; the boundaries ill-defined; great tenderness on pressure; no redness; the skin not adherent; no signs of pointing. Nothing could be dis-

¹ Reinstadler. Arch. für exper. Pathologie und Pharmakologie, Bd. 11, s. 103.

² Read before the Suffolk District Medical Society, April 30, 1881.

covered by the rectum, except great tenderness on the right side of the pelvis. The pulse was 120; temperature not much elevated; appetite good.

Dr. Beach was not inclined to urge an operation, because he strongly suspected that some disease of the bone was at the bottom of the trouble, because there was no indication of adhesion between the skin and the tumor, no sign of pointing anywhere. Moreover the symptoms were not urgent, there was no general peritonitis, no failure of strength. There was a strong probability that any incision would open into the peritoneal cavity, and on the other hand a good chance that the abscess might open into the bladder or rectum, or pass under Poupart's ligament and open in the thigh. There was in fact great pain along the course of the anterior crural nerve; great tenderness and some swelling in Scarpa's triangle. The thigh measured one inch more, at this point, than the other thigh. Palliative treatment was therefore employed, cataplasms, injections with oleate of morphia, two per cent. solution; rest, morphia hypodermically, etc.

Four days afterward, February 13th, on the twenty-first day, the abscess broke into the bladder. The skin over it had never become adherent, and there was no sign of pointing externally. A large amount of pus was discharged with the urine, the tumor rapidly disappeared, and no point showed dullness any longer. The acute suffering of the patient was greatly relieved, and hopes of recovery were entertained.

Six grains of quinine were taken daily, with whisky, beef tea, etc. In three days there was slight improvement as far as regards strength, but still the temperature remained at the same point, 102° F., the pulse was always about 120, there was still a large discharge of pus with the urine; this, however, had no very bad odor. So the case dragged along for two weeks longer until at the beginning of the fifth week of the illness the patient grew worse. A slough formed under the right heel and another on the sacrum, the urine acquired a horrible odor, the strength failed, the pulse rose to 140. Finally on March 3d all pain ceased, patient thought he was dying, and sent for me in the night to say good-by. There seemed to be no special cause for this prostration, no chill at any time, only great pain in the right thigh and in urinating for the last few days. The quinine was increased to twenty-five grains daily, and for several days a pint of brandy daily was consumed.

The patient rallied, the back and heel were relieved by an air bed, poultices were applied continuously to Scarpa's triangle, where an attempt at pointing was apparent, and ten days later, on March 13th, an incision was made just over the suppurous opening. At least a quart of urine and foul pus was evacuated, a catheter introduced into the incision passed seven inches downwards and towards the sacro-iliac articulation. The whole cavity was washed out with phenyle and water, and this answered very well as a disinfectant. A large drainage tube, five inches long, was introduced and left in the wound, and supporting treatment continued. To make a long story short, the patient lingered three weeks with pulse ranging from 110 to 180, consuming fifteen to twenty five grains of quinine daily, with plenty of whisky and Miller's export beer, which is better than lager for such cases. The wound was daily washed out, and the great slough on the sacrum treated with ichthodol. The liver was observed to be hugely enlarged, the lungs normal, emaciation terrible.

On April 4th the patient died, after terrible suffering, ten weeks and two days from the first signs of trouble.

The autopsy was held twenty-four hours after death. The heart and lungs were normal; immense slough over sacrum; the kidneys largely swollen, cloudy, hyperemic; the liver hugely enlarged, fatty, yellow; no general peritonitis; in region of cæcum the intestine was adherent to the lateral abdominal wall; the drainage tube lay in a channel passing down towards the spine, crossing the common iliac vessels, and lying on the psoas; no dead bone could be found anywhere in connection with this tract. Deeper down in the pelvis the bladder had a perforation opening into a sloughy cavity which extended down to the sacro-iliac synarthrosis; this was denuded, as was also the ramus of the ischium; the finger could be passed down and out of the pelvis, under the ramus, passing into another sloughy cavity outside the pelvis, in the thigh; the lining of the bladder was very sloughy. On opening the thigh a huge cavity was found connecting indirectly with the original point of incision, and directly with the pelvis under the ramus of the ischium. The whole acetabulum and head of the femur, with the trochanters, was denuded and carious; the cavity extended nearly to the knee and posteriorly into the buttock, and was full of foul pus and sloughy tissues. It could not be washed out by the drainage tube, and was apparently formed by the urine sinking in the pelvis, passing out of the latter under the ramus, and then destroying the inter-muscular connective tissues very extensively in the thigh, hip, and buttock.

It is hard to see how any practicable counter-incision or system of drainage could have prevented this, and yet it would seem that it was the extravasation of urine and the consequent destruction which carried off the patient rather than the original abscess first felt in the right iliac fossa.

There are several points of interest connected with this case, and first as to the probable advantage which might have been derived from an incision in the iliac region. It did not appear from the autopsy that there was any denuded bone above the pelvis, the intestine was not perforated, the appendix was normal, there was never any great derangement of the action of the bowels.

An incision carried down to the tumor would probably have opened the peritoneal cavity, although possibly it could have been made external to and behind it; in that case there is some chance that the patient would have weathered the attendant risks of cellulitis and peritonitis, and escaped.

After the abscess opened into the bladder it soon became evident that it was not fully discharging its contents, and that in all probability urine must be escaping into the tissues. Now if some means of draining and washing out the cavity could have been devised before the injury became too extensive, the patient might have recovered. This question must come up, not infrequently, in connection with wounds and injuries of the bladder, and abscesses opening into it, and with modern advances in antiseptic surgery it might be possible to do something. Especially in cases of women an opening into the vagina drains the pelvis readily, and in this case the urine had worked its way under the muscles and was pointing at the inside of the tuberosity of the ischium when death occurred. An attempt was made to keep a catheter in the bladder, but it was not tolerated. The

effect of large doses of quinine, twenty-five grains daily, was very marked in this case, prolonging life apparently for several weeks after the patient was almost moribund; in cases not necessarily fatal it must often have the power of tiding over the critical time until convalescence can set in. During the last week a pellicle of oil was observed several times on the urine, and although nothing in amount to compare with a case of oily urine which I recently reported, it was correctly held to indicate extensive destruction of tissue by the urine. If the patient had not been already so emaciated there would probably have been more oil observable on the urine.

RECENT PROGRESS IN THE TREATMENT OF CHILDREN'S DISEASES.¹

BY D. H. HAYDEN, M. D.

TREATMENT OF PLEURISY IN CHILDREN.²

At a meeting of the New York Academy of Medicine, held March 24, 1881, Dr. J. Lewis Smith read a paper on the above subject, in which he spoke of the treatment appropriate to each of the three stages:—

(1) The stage which precedes the effusion; (2) the stage of effusion; and (3) the stage of absorption and convalescence.

In the beginning of the disease measures should be adopted which are appropriate for reducing inflammation and limiting exudation. The abstraction of blood, in idiopathic pleurisy, may be beneficial if judiciously employed, but only one or two or three leeches should be employed in a robust child two, three, or four years old. As a rule, the loss of blood is injurious in all cases of secondary pleurisy, such as follows scarlet fever, etc., and also if the quantity of effusion is great. Emollient and simply irritating poultices are serviceable in the first stage, and he recommends a mixture of one part of mustard to sixteen of linseed. It should be made very wet, spread thin, applied over the chest in front and behind, covered with oil-silk, and changed twice in twenty-four hours. For children under six or seven months of age rubbing the chest with camphorated oil and applying a simple poultice may be sufficient.

Blistering at this early stage of the disease should not be employed, as it increases the inflammation, and Dr. Smith has seen a case which terminated fatally, in which there was found an increased area of inflammation corresponding exactly in situation, size, and shape to a blister that had been applied.

The indications for the use of internal remedies in the first stage are to diminish the frequency of the pulse, relieve the pain, and allay the cough.

To a child *three* years old the tincture of aconite may be given in doses of half a drop, and for a child *six* years old in doses of *one* drop every three hours for two or three days. In the first stage of primary pleurisy the cardiac sedatives may be used; but digitalis is a safer and better remedy in all other cases, and it also can be used in the second stage.

To a child two years old the tincture of digitalis may be given in doses of *one drop every three hours*, and to a child five years old *two* drops with the same interval. An opiate is ordinarily required: Dover's

powder, one to three grains, every three hours. Hyoscyamus may be used to relieve the pain and cough; digitalis may be combined with an opiate, and morphine and aconite may be combined. In secondary pleurisy digitalis is preferable to aconite.

In the second stage, unless the effusion is small, measures designed to remove it are required. The propriety of using blisters in this stage is very doubtful. A relaxed condition of the bowels favors absorption of serous effusion. Diaphoretics do not aid much in the removal of fluid. Pilocarpine produces a depressing effect, which renders it unsafe.

Diuretics and tonics are beneficial. Digitalis, with the acetate of potash, is very serviceable.

R̄ Infus. digitalis ʒiv.
Potass. acetat. ʒi. M.

S. Teaspoonful every three hours to a child four or five years old.

Bitter tonics are especially useful in this stage, and the acetate of potash may be combined with a decoction of cinchona with good results. A full amount of nutriment should be taken, with but little fluid. Of course, the suggestion to use a dry diet and diminish the quantity of drink is not applicable to young children. If the appetite and the general health are good, and there are no symptoms due to the presence of the fluid, but little medication is necessary. If there are such symptoms and the fluid does not disappear, the question of surgical interference arises, and the indications for it are the following:—

(1.) Oppressed breathing, due to the liquid present, whether it be sero-fibrinous, purulent, or hæmorrhagic.

(2.) If there be flat percussion-note over the entire affected side, with displacement of the heart, even if there be no dyspnoea, for the latter may occur suddenly.

(3.) Moderate effusion, without material decrease in quantity by absorption after some weeks of treatment. There is danger that catarrhal pneumonia, terminating in cheesy pneumonia and tuberculosis, may occur in portions of the compressed lung. Besides, the longer the lung is compressed the slower will it return to normal expansion after the pressure has been removed.

(4.) A moderate quantity of fluid coexisting with disease of the opposite lung, or of the lung of the affected side.

(5.) Extension of the inflammation to the pericardium. Pericarditis as an extension of the inflammation is not infrequent.

(6.) The existence of valvular disease of the heart.

(7.) The presence of pus, empyema.

Dr. Smith recommends the eighth intercostal space, perpendicular to the angle of the scapula, for the place of puncture. The thickness of the thoracic wall is one half inch; in emaciated children it is less. Introduction of the canula to the depth of one inch is sufficient to pass beyond the exudation and allow the liquid to flow through the canula. Dr. Smith does not mention the operation of making a permanent opening, except to speak with disfavor of ever excising a portion of the rib for this purpose. Washing out the cavity he disapproves of as unnecessary, except where the pus is offensive.

ON MILK-INDIGESTION IN YOUNG CHILDREN.³

Children who are brought up in the usual way, upon milk and milky foods, may suddenly begin to ex-

¹ Concluded from page 57.

² New York Medical Record, April 9, 1881.

³ Eustace Smith, M. D., F. R. C. P. London, British Medical Journal, June 4, 1881.

hibit symptoms of indigestion, which renders an immediate change in their diet indispensable if serious consequences are to be avoided. In hand-fed babies this unfortunate accident is common enough, and the mortality amongst such infants may be in a great measure attributed to it. The same thing may occur, however, in children who have been weaned at the usual age, and it is therefore sometimes met with in young children twelve or eighteen months old.

The inability to digest cow's milk is usually a temporary infirmity, arising from some casual derangement of the stomach and bowels. In other and less common cases the fault is in the milk. Thus infants who are weaned very young often find cow's milk to be beyond their powers of digestion, and unless special precautions be taken to adapt it to their immature organs serious consequences may ensue.

Other causes may make cow's milk appear to be indigestible. Thus the child may be overfed, its meals being too large or too frequently repeated; or the feeding apparatus may have been neglected, so that fresh milk put into a dirty bottle may have begun to ferment before the child swallows it. These causes may, however, be put on one side. The kind of milk-indigestion now spoken of is that in which, for whatever reason, a perfectly pure, fresh milk, given in suitable quantities, and with all possible precautions to make it digestible, is found to disagree. The author divides the general symptoms into three classes, according as to whether the prominent feature is constipation, vomiting, or diarrhoea. Cases where *constipation* is a marked symptom are generally found amongst young infants. The motions are scanty and rare. The bowels sometimes remain confined for twenty-four hours or longer, and when they are at last relieved hard, clay-colored balls, stained with green mucus, are expelled with great effort and straining. These balls consist of masses of hard curd.

A full dose of oil, which clears away the curd, allays the symptoms for a time, but usually, if the milk diet be continued without any change, they return in a day or two, and the child is in the same distress as before.

It is usually in cases of artificial feeding that these symptoms are found; but sometimes, although rarely, we see them in children who are nursed at the breast. When the indigestion is due to catarrh of the stomach it is readily amenable to treatment. All that is necessary is to put a stop to the milk for a day or two, and to clear away undigested curd by a full dose of castor oil. It, however, the fault be in the milk, and not in the digestive organs of the child, some change in the method of feeding is indispensable.

The author reports a curious instance of this difficulty in a boy seven months old. The child had been suffering for some weeks from severe abdominal pains; his bowels were very confined, and the motions consisted almost entirely of curd. He was taking nothing but the breast. Aperients had been found to relieve the child for a time, but the symptoms always returned when the effect of the purgative had passed away. Whenever the breast was stopped for a few days he immediately improved, but relapsed as soon as suckling was resumed. The child was evidently suffering from inability to digest the curd of his mother's milk, and it became a matter of the greatest importance to do so, otherwise he would have to be weaned, and fed in a different way. Attempts had been made by medication of the mother and modification of her

diet to alter the quality of her milk, but without success. The intervals between the times of suckling were increased; alternate meals of barley water were given from a feeding-bottle, and the quantity of milk taken in the course of the day thus diminished. No improvement, however, followed, but the griping and fretfulness continued. The plan was at last adopted of giving the child barley water from a bottle immediately before he took the breast. This method succeeded perfectly, and the child had no further unpleasant symptoms. In this instance the infant's stomach was in a perfectly healthy state. The fault lay in the mother's milk, which was too heavy for the child's power of digestion. Should this happen in the case of a wet-nurse the nurse must be changed, or the child be weaned and brought up by hand.

In the large majority of cases of milk-indigestion in infants reared at the breast the fault is in the digestive organs of the child, an attack of gastric catarrh having rendered him, for the time, incapable of digesting his mother's milk. In these cases the indigestion is a temporary failing, and is easily remedied by suitable treatment. Without judicious management the derangement may be prolonged indefinitely, and it not infrequently happens that the mother is ordered to wean her baby under the mistaken notion that her milk is unfit for its support.

In cases of gastric catarrh, where the complaint is acute and severe, *vomiting* is usually the most prominent symptom. Under such circumstances milk becomes a positive poison. The author reports a case of this kind in an infant two months old. She had been brought up by hand, and was being fed upon milk and barley water in equal proportions. The child was ordered to be kept warm and perfectly quiet. A weak mustard poultice was applied for an hour to the epigastrium. The milk was stopped, and the child was fed with weak veal broth and thin barley water mixed together in equal proportions, and given cold, at intervals, with a teaspoon. A few drops of brandy were given occasionally, as seemed desirable. The progress was steady to recovery. The most important part of the treatment was the substitution of veal broth and barley water for the milk. Directly the supply of fermentable matter was stopped, fermentation ceased, acid was no longer formed, and the digestive organs returned to a healthy condition. In contrast to this acute case the author then reports a case where the complaint was chronic, the inability to digest cow's milk having extended over a lengthened period.

Gastric and intestinal disorders, like the second case reported by the author, often date from the time of weaning, a catarrh of the stomach being set up by the abrupt change from human milk to artificial feeding. Such cases are readily treated, however severe may be the vomiting, by restricting the diet to equal parts of veal broth and thin barley water, given cold in small quantities at a time, by warmth to the belly and extremities, by perfect quiet, and by suitable remedies. According to Dr. Smith the best sedative is liquor arsenicalis, half a drop for a dose, given with a few grains of bicarbonate of soda in some aromatic water. After a few days of such treatment the power of digesting milk usually returns, but at first it should be given sparingly, freely diluted with barley water, and only once or twice in the day.

The class of cases in which *looseness* of the bowels is the prominent symptom is then described by the

author. The stools are not at first watery; for a time the motions are semi-solid, and have the color and consistence of putty. There ensues a gradual loss of flesh. If proper treatment be not resorted to the case becomes one of obstinate chronic diarrhoea, or else the child falls an easy victim to some intercurrent disease.

Such cases in the early stage are often spoken of as cases of "inactive liver," the white stools being supposed to be merely the result of insufficient biliary secretion. Cholagogues are, however, in such cases quite useless. A dose of gray powder produces, perhaps, one dark stool, but afterwards the motions are of the same character as before. When a chronic diarrhoea is regularly established the cases are often called "consumption of the bowels." It is needless to say that they have no relation at all to "consumption," but are a purely functional derangement, a chronic catarrh of the bowels, excited and maintained by undigested food. The post-mortem appearances, except for the wasting of all the tissues, differ very little from those in health, but in long-standing cases we may find ulceration of the bowels. There is, however, no sign of gray tubercle.

The author reports a typical one of these cases in a young girl, aged fourteen months, with an intestinal catarrh and gradual loss of flesh of two months' duration. The treatment adopted consisted of exclusion of milk from the diet, and the child was fed with whey and cream, veal broth and barley water, yolk of egg, and Mellin's food dissolved in barley water. She took at first an alkaline solution of iron with half a drop of liquor arsenicalis in each dose. This was afterwards changed to quinine dissolved in iron wine, and cod-liver oil, and it was not long before the child was convalescent.

In all cases of functional derangement in children the tendency is to recovery if nature be allowed her way. This is especially true of derangements affecting the alimentary canal. If the irritant, whatever it may be, which is the cause of the disturbance be removed, the organs quickly resume the normal exercise of their functions. Unfortunately, well-meant efforts to relieve the distress are often themselves the cause of its continuance. The child is weakly and wasting, therefore he requires nourishment, but the utmost care must be exercised in selecting the kind of food to be given. To continue the supply of fermentable food when the stomach and bowels are already filled with the products of fermentation is a certain way of hindering the patient's restoration to health. If, on the contrary, we cut off the supply of fermentable matter, unless the strength be too much reduced, recovery follows as a natural consequence. In such cases milk and the ordinary farinaceous foods must, for a time, be withdrawn from the diet. The best substitutes are those which have been mentioned, namely, weak veal broth and barley water, in equal proportions, cream and whey, a dessert-spoonful to four ounces, yolk of egg (beaten up, in the case of infants, with whey or veal broth), and Mellin's food for infants, dissolved in barley water or in equal parts of this and whey. Veal broth or chicken broth is better than beef tea, for the latter is often irritating to the digestive organs of young children, especially if there be any diarrhoea.

Sometimes when cow's milk cannot be digested ass's or goat's milk is more successful, and sometimes a child, much reduced by digestive disturbance dependent upon

an unsuitable dietary, at once recovers when put again to the breast. More often, however, milk of any kind seems to act as an irritant poison, and no hope of relief can be entertained until it is excluded from the diet.

Hospital Practice and Clinical Memoranda.

AN UNUSUAL CASE OF STRANGULATED HERNIA.

BY GEORGE JEWETT, M. D., FITCHBURG.

WAS summoned at midnight, April 9, 1881, to visit a patient of Dr. W. H. H. Shepard in Westminster, from whom I learned the following facts:—

The patient, Mr. Perkins, was about fifty-five years old; had left inguinal hernia for many years, for which he had worn an ordinary truss with perfect relief until within the past four months, since which time the use of truss was unsatisfactory, and he became aware that the hernia could not be fully reduced. April 7th went to bed well; on the morning of the 8th felt pain at epigastrium, with nausea, when the hernia appeared in an unusually large volume, filling the scrotum. He observed it was larger and harder than ever before, but reduced it entirely, as it seemed to him, without much difficulty. He remained quiet the remainder of the day, nothing occurring until the afternoon of the 9th, when the hernia reappeared larger and harder than ever, and could not be reduced. He soon sent for his physician, who also failed in taxis. At time of my visit there was prostration, nausea, but not much vomiting. The tumor was large, very hard, and not resonant, nor markedly tender. Without effort at taxis I introduced an aspirator needle, and drew, by estimate, about five ounces of bloody serum, which soon coagulated upon standing. Decided to give opiates, apply ice, and wait till morning. Nine A. M. Patient had nausea; not much pain; had slept some; hands and feet cyanosed and cool; nose and ears cool; was evidently sinking. The hernial tumor was still larger, apparently solid. The patient etherized, instruments and hands carbolized, I proceeded to operate without delay. The tissues covering sac were much infiltrated. On opening the sac a jet of bloody serum spurted freely, and a coil of intestine, livid in color, was exposed; two or three long, well organized clots were floating in the serum.

A careful examination of the strangulated gut showed the serous coat had been stripped off for a space one inch in width and two in length. The outer margin revealed a thickened mass of lymph, which had glued the intestine to the scrotal wall, and recently had been torn from its connections. A bloody serum oozed from the abraded surface. The stricture was high up, and when relieved the intestine could not be fully returned. Exploring the region of the obstruction, I found a fibrous band binding the intestine to the abdominal wall as far as I could reach. This I carefully separated as far as possible with my index finger, cleansed and carbolized the parts, and returned the contents to the abdomen without further difficulty. The cut surfaces were carefully cleansed, and as the wound was partially closed the patient began to cough, when considerable bloody serum and clots were forced from the abdominal cavity. After some further delay

the dressing was completed. The patient made a good recovery, and a month or thereabout after expressed himself in good condition for business.

New Instruments.

ON THE USE OF JENNISON'S TUBE.

BY J. VINCENT SMITH, M. D., MELROSE.

THE accompanying engraving gives a very good idea of a new instrument for intra-uterine injections, invented by Mr. C. R. Jennison, of Boston, about two years ago, which greatly reduces the dangers of a very useful method of treatment of some of the morbid conditions of the body of the uterus.

Figure 1 shows the tube as it should be when introduced; Figure 2 when *in situ* and operating. It consists of a curved canula, A, on which is a sliding gauge, B, by means of which the distance that the canula is introduced into the uterus may be known. C is a tube connecting with a Davidson syringe at one end and terminating at the other in a bulb, having lateral openings which are covered by the canula when in position for introduction. When the instrument has been introduced to the desired distance the tube is advanced toward the fundus and the fluid injected. The openings are of fine calibre and so made that they throw the liquid obliquely backward. Some of the advantages of Jennison's tube are: that the preliminary dilatation of the cervix is not required, the canula affording a very free exit for all the fluid that can be forced through the tube, and therefore the injection may be used at once when occasion demands; that it prevents the fluid from striking the fundus, and that the fine openings so pulverize it as to preclude the possibility

of its striking any part forcibly; that it may be used in cases of flexion where it is not safe to use injections by ordinary means even after dilatation.

Topical applications in the form of injected fluids undoubtedly afford the most effectual agency for treating the leucorrhœa that results from a granular condition of the mucous membrane. The effect is more uniform and efficient than can be attained by the use of crayons, solid agents, or cotton wrapped about a sound and saturated with the remedy, as recommended by Playfair, for the latter either act unequally or become so coated with mucus as to be rendered inert. But this method of treatment has been followed by bad results in so many instances that it is now seldom used except in cases of metrorrhagia. The principal cause of these results, however, is that the fluid is prevented from escaping freely, either by a return of the flexion, where flexion exists, or by contraction of the cervix, which may take place when fluids are injected into the uterus even though it has previously been thoroughly dilated.

To avoid the danger that attends the use of intra-uterine injections the fluid must not impinge the fundus, it must enter the uterus in fine jets in order that it may strike the inner surface with the utmost gentleness, and a perfectly free exit must be provided so as not to distend it. These requirements are fulfilled by the invention of Mr. C. R. Jennison. I have used this tube in a large number of cases without having seen any disagreeable results whatever from its use, and I commend it to the attention of the profession as a valuable addition to the armamentarium of the gynecologist.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

ANNUAL meeting April 30, 1881, Dr. F. W. DRAPER in the chair. Seventy-nine members present.

Dr. W. F. WHITNEY read a paper entitled *The Inoculability of Tuberculosis*. Vide page 75 of the JOURNAL.

Dr. E. W. CUSHING said that although it would be impossible to arrive at any exact conclusion from the experiments detailed by the reader, he agreed that it was incumbent upon the physician to caution any one inhaling the air expired by a tuberculous person. There was a wide-spread belief among the laity that tuberculosis was contagious, and he thought that almost every one in active practice had seen cases which seemed to support this theory, even if not sufficient for proof.

Dr. E. W. CUSHING reported a case of abdominal abscess in right iliac and inguinal region. Vide page 79 of the JOURNAL.

Dr. H. W. BROUGHTON asked if the large doses of quinine had given rise to any disagreeable symptoms.

Dr. CUSHING replied that some tinnitus aurium had been complained of from twenty-five grains, which disappeared when the dose was reduced to eighteen grains.

Dr. F. C. SHATTUCK said that his experience had led him to the same conclusions with regard to the tolerance of and benefit from large and continued doses of quinine in some cases; he instanced a case of em-

pyema bursting into a bronchial tube, in which ten grains were given thrice daily for more than a fortnight, before any ringing in the ears was noticed. The patient finally recovered completely, and it certainly seemed as if the quinine tided him over a very critical time.

Dr. G. H. LYMAN spoke of the use of hydrobromic acid as a solvent of quinine, and stated that it diminished the unpleasant effects of quinine. He did not consider twenty-five grains a particularly large dose to administer per diem in a case where there was any septic element to contend against.

Dr. D. HUNT called attention to the fact that blindness and deafness were both known to occasionally follow the use of quinine in doses much smaller even than had been mentioned by the previous speakers. He thought that often other tonics might be used as succedanea which did not have this demerit.

Dr. LYMAN remarked that he had often used salicylic acid in large doses in place of quinine, but had found the same unpleasant effects; referring to Dr. Hunt's remarks, Dr. Lyman thought the danger of giving quinine was rather in its long continuance, even in small doses, than in cases where we had to deal with such a disease as septicemia; personally he should fear the effect of one grain thrice daily given merely as an ordinary tonic more than sixty grains where there was septic condition to counteract.

Dr. WATERMAN asked if it might not have been possible to drain the abscess by keeping a catheter in the bladder.

Dr. CUSHING replied that the idea was entertained at the time, but found impracticable on account of the swelling and tenderness of the urethra.

Dr. T. S. BILLINGS, M. V., present by invitation, read a paper entitled *The Foundation of Veterinary Institutions in the United States*, of which the following is an abstract:—

Veterinary like human medicine traces its descent from the Aryan people, Choraha, one of the earliest of Hindoo medical writers, having been accredited with writing upon animal diseases. The history of veterinary medicine may be logically divided into two periods, the ante-scholastic and the scholastic, the first extending from the earliest dates of medical history to the year 1762, which marks the introduction of the second with the foundation of the first veterinary school at Lyons, France.

The schools of Europe are all governmental, founded, funded, and controlled by the respective governments. Those of Britain, like our medical schools, are private and, in a certain sense, irresponsible institutions. The cause leading to the establishment of the European schools was not, as many might suppose, the desire to educate a large number of practical veterinarians, but they were called into being to educate men capable of studying into the source and nature of those terrible animal pests which had been the scourge of Europe for centuries, and against which the practical empiricism which had until then existed had been proven to be powerless.

In this country we are still over a century behind the best countries of Europe in reference to veterinary medicine. We have not only to make laws for the suppression of contagious diseases, but to supply means for the education of young men suitable to execute them. While the countries of Europe had only to face the question of the suppression of the strictly pure animal pests, the progress of time has developed a new and very

important field for the veterinarian of our day, which is not of secondary importance to the former, namely, his part as a public hygienist in the study of the nature of those diseases of our animals, and diseased conditions, which bear an important relation to the public health, such as anthrax, tuberculosis of cattle, milk supply, trichiniasis, etc.

In this country we have also another very important question to consider, which those of the continent of Europe have escaped, namely, whether it is more likely to best serve the public good that laws for the suppression of the contagious animal diseases be of a national or state character, and the same is true of schools or a school for the education of veterinarians.

The fact of the transportability of diseased animals, and the natural desire of drovers to rid themselves of such, and the danger of the extension of infectious diseases by this means, makes it at once apparent that state laws, with their natural nonconformity, can never realize the desired end; hence it seems best that a national code of laws, leaving the execution of the same to the state authorities, is the only plan by which this end can be attained. Those veterinary hygienic laws which have to do with the prevention of human diseases may naturally be left to the respective States. The question of a national as opposed to our present plan of chartered private schools for the education of veterinary students is one which should also have serious consideration, and which must result in favor of a national school, to every unprejudiced mind. The evils which now exist with reference to our medical schools can only so be avoided. We should then have but one standard of education, and the public would have the best means possible of knowing that the American educated veterinarians had received something like a uniform education. The sad rivalry for students which now exists between medical schools could not then come to pass, and the country could not then be flooded with a whole army of incompetent practitioners, as is now the case in human medicine.

That the medical profession occupy a very responsible position in influencing the people and legislation in regard to these questions is indisputable, and it is to be hoped that it will not be found wanting as to this duty.

Officers were elected for the ensuing year.

PROCEEDINGS OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED meeting second Thursday of May. Vice-President Marcy in the chair.

Dr. MARCY read by appointment a paper on *Abdominal Surgery*. The grand advance which general surgery has made during the last fifteen years he attributed in part to a better knowledge of diseased processes, and preëminently to such practical researches as those of Professor Lister. Until the present century, gastrotomy was limited to exigencies requiring the delivery of a child by abdominal section, and to operation for strangulated hernia. The triumphs of the ovariologist have done more than all other combined causes to remove the fallacious opinion, so long and universally held, that the peritonæum was sacred from the surgeon's knife. "Now, with suitable precautions, the peritonæum is subjected to surgical manipula-

tions almost without fear or danger;" but hereas elsewhere must be combined "that much rarer talent, a discriminating judgment and sound common sense, to be exercised as to the *where and how* of operative interference, supplemented with a belief in and familiarity with the antiseptic treatment of wounds."

First, operations confined to the abdominal wall, including wounds, which should be carefully closed, after attention has been given to the underlying cavity and contents. Second, exploratory incisions, freely practiced to gain surer information of the condition of organs; and still again, operations undertaken for the various hernias, the many failures in which have always been an opprobrium of the surgeon.

Antiseptic surgery is believed to offer a sure and safe cure for hernia. An operation devised by the author was illustrated by the following report:—

Mrs. M., fifty-five years of age, had had several children, had presented umbilical hernia since birth of a child, eighteen years before; sometimes troublesome but generally cured for without difficulty; had never worn truss. Abdominal walls very fat. Finally, had an attack of unusual distress and could not reduce the tumor. First seen by the doctor after twenty-four hours. In bed, suffering severe pain, tumor of size of a small orange, tense, gurgles on pressure, surface red and abraded from efforts at taxis. Failing in manipulation, gave ether, dissected superjacent tissues from sac covering tumor, and, opening the ring, attempted reduction without entering the peritoneal cavity. Failing in this, cut open the sac, which contained, *inter alia*, a coil of intestine four inches long, of a dark purple color. Intestines were generally much distended with gas, and gave trouble by protruding at the wound. The sac was excised, the peritoneum carefully adjusted with (caribou) carbolized suture, deep silver suture added with the lead button, and the superficial wound was closed by silk, a drainage tube being placed in the pocketed wound; the entire operation being done under the completest antiseptic protection.

Nausea and vomiting ceased at once after the operation, and the record of a week following showed the thermometer at no observation to exceed 100° F., at the end of which time the pulse was 84, and the temperature 99.4° F. Hereupon, removed drainage tube and button sutures, retaining the wire loosely twisted. Wound completely closed, and dressings scarcely stained. Slight troubles appeared a few days later, but the patient made a good recovery, and the operation was a success.

This is illustrated an operation first done by the writer in 1870, and since many times repeated with the happiest results. It consists in exposing the rings, refreshing the parts, if the sac is large, generally excising it, carefully bringing the peritoneum into coaptation with the continuous suture of catgut, closing the rings in a similar manner, and pocketing by external sutures. The catgut not only holds the parts in favorable apposition, but is replaced by connective tissue, thus furnishing bands of permanent reinforcement. Quite lately, tendinous ligatures have been substituted, as they are believed to remain longer unchanged.

In a glance at ovariectomy, emphasis was laid upon the remarkable diminution in mortality from the operation within the last ten to fifteen years, as illustrated by the latest statistics of Spencer Wells and others. Especial attention was called to a recent contribution by Dr. No. 2207th, entitled *A New Method of Per-*

forming Ovariectomy, in which, among other points, he discusses the danger of the patient from shock, which he regards but another name for reduction of temperature,—the result of peritoneal exposure. Another entirely new modification of previous practice was the immersion of a patient in an antiseptic bath, after operation, in order to obviate the dangers which in severe and complicated cases may ensue from defective drainage from the peritoneal cavity. The writer closed this part of his paper with appropriate allusion to the labors in this field of the late president of the society, the younger Storer.

After allusion to the treatment of uterine tumors, with statistics, also to Freund's operation, the operation of Poro of Pavia was instanced, which provided for the removal of the pregnant uterus; mother and child both saved. Isaac Taylor, a year ago, in New York, reported a successful case by a modified method, the main features of which were detailed. A recent total of thirty-six cases by Poro's method gives as results the survival of nineteen mothers and twenty-six children.

The expedient which abdominal surgery offers for tubal pregnancy and the points of Battey's operation having been briefly reviewed, a survey of measures of surgical interference, other than such as pertain to gynecic surgery, closed the paper; and first, reference was made to the treatment of acute perforation, typhlitis, etc., and brief statistics were given. Removal of the spleen, first successfully done in Italy, in 1519, has its grave dangers much lessened by our modern antiseptic methods. A similar remark applies to nephrotomy also. Revised statistics give, of the latter operation, thirteen recoveries and nine deaths; but of the deaths two cases were so severe as to have been left unfinished.

Among later triumphs may be included Billroth's resection of the stomach for cancer. Koeberle recently removed two metres of the small intestine for multiple strictures, with recovery. Czerny, in 1880, removed two portions of the large intestine for cancer, with recovery from the operation; and Reybord, in 1833, removed four inches of cancerous descending colon with like happy result. The author closed his survey with eloquent expressions of his hopes and expectations from the surgery of the future, which must effectively solve the problem of safe and final relief for the sufferer from fibroid tumors of the uterus.

The paper being before the society for discussion, Dr. CLARKE recalled a case of strangulated hernia, eleven years ago, treated by Dr. Marcy and himself; it was extreme in every way and complicated with asthma. This was one of the first operations in which he had witnessed resort to antiseptic surgery. Result, satisfactory in every way. Here catgut was used with intent of its disappearance by absorption. The temperature hardly went up at all after the operation.

Dr. W. S. BROWN practically distinguished two classes of cancer, whether of stomach, intestine, or wherever developed: first, the case in early stage, when disease may still be strictly local, and second, the case farther advanced, and involving constitutional impregnation. Under latter circumstances should refuse to operate, except when an operation was demanded, the patient intelligently appreciating probabilities. We can promise little better than a brief respite, with expense and risk thrown in.

Dr. WARNER agreed with Dr. Brown in the main. As the physician gets older and loses or has had grati-

fied a portion of his early ambition, he is less disposed to operate in true cancer, except at the urgent intercession of the patient; for if it is true cancer we know it will return. Many things are to be considered in abdominal section and removal of a portion of the intestine. Should never operate, in whatever degree of urgency, unless we are sure we can make the patient more comfortable, but in ovarian tumor there is but one opinion among the intelligent, — make the attempt of removal, and this even in a bad case. As to fibroid, the day is coming when we shall have a better system of surgery than now. Was very much interested lately in Dr. Thomas's illustrations of the work of his scoposaw, and his remarks on the same.

Dr. BROWN still further illustrated his position respecting the two stages of cancer. Twelve years ago he had operated upon a cancerous breast, in its early development, and it had never returned.

Dr. WARNER recalled a case which came to his knowledge in his early residence in Boston. A tumor was removed from a patient, which four surgeons pronounced to be cancer, but which subsequent expert investigation showed to be non-malignant. The character of a tumor, especially in its early stages, is difficult to determine; if its removal is not followed by a return of the disease should doubt its being cancer at all except upon positive evidence. A lady in Lowell had almost the entire breast removed twenty-five years ago, and had enjoyed uninterrupted health since until lately, when death resulted from some form of malignant disease of a portion of the liver or of the pyloric orifice. This was the longest respite he had ever known. Had removed and helped remove many cancers during the period of his association with Dr. Storer, and not one tells a favorable story. In one case had operated greatly against his judgment; wound healed kindly, but the disease soon returned in a more virulent form than at first, and patient died rapidly. Charlotte Cushman's history illustrates this principle. The doctor gave several other illustrative cases.

Dr. CLARKE asked how long the interval was between operation and return of the disease.

Dr. WARNER replied, with some only a few weeks; a few may go three to five years.

Dr. M. L. BROWN gave a general average of two and one half years.

Dr. WEEKS considered the value of antiseptic surgery to be especially established in hernias, and we expect much from it in twists and in typhilitis. Did not see, in fibroids, why we may not cut down and excise as we would other growths, especially if they be external and subperitoneal.

Dr. FRISBIE testified to the value of antiseptic methods in surgery. Seriously doubted the policy of operating in any form or stage of cancer, but would inquire whether the cancer was likely to return any sooner if it were located internally, as in the uterus or the stomach.

Dr. WARNER replied, more rapidly as respects the uterus; was uninformed as to the stomach. The doctor recalled an instance in which he had operated for cancer of the neck of the uterus. Had felt very hopeful of results, but disease soon returned with new malignity, and speedily pervaded and consumed the whole organ.

Dr. NORRIS gave the details of an operation he had lately witnessed for hernia by Heaton's method. Result favorable and gratifying. Success seemed to

depend both upon acupuncture and also the insertion of a mixture containing extract quercus alba, alcohol, ether, and morphia in certain fixed proportions.

Dr. WARNER believed much depended upon the needle, which was made in a peculiar way, and, if he was rightly informed, was somewhat barbed, and designed to tear somewhat as it was withdrawn, and so help set up adhesive inflammation.

Dr. MARCY added that a surgeon in Philadelphia had pursued a series of cases operated upon by Heaton's method, and for a time was enthusiastic over results, but later observation had obliged him, in a large measure, to retract and candidly confess his disappointment.

Dr. CLARKE reported a case of strangulated hernia, where intervention of the aspirator made taxis possible, but tumor in due time returned.

Dr. MARCY, in closing the discussion, quoted Dr. Sims as recently declaring that antiseptics had done for abdominal surgery what nothing else could have done. Why cannot we make full use of this resource in operating on fibroids? Take a thoroughly antiseptic room, wash patient with a solution of carbolic acid, keep the acid evaporating from the furnace or otherwise during the operation, and throw spray upon the walls. In a recent case he had attempted the removal of a fibroid, intending to excise and leave the uterus behind; was obliged to desist on account of unforeseen obstacles, which were detailed in the report. Closed the wound, and left patient as comfortable as possible: there was no rise of temperature, and patient was practically well in one week.

As to the removal of cancerous growths from the abdominal cavity, he was taught by Bennett that cancer is, originally, a local disease, and this he still believed. Was cognizant of instances of removal, wherein the disease had not yet recurred for eight or nine years. The doctor cited other cases in illustration. Had removed the whole breast presenting a tumor of the size of the fist; a few weeks afterward swollen glands appeared in the axilla, whereupon he reopened the incision, and removed both all cicatricial tissue and the entire glands. Operation a success. In other cases whose event had been less fortunate he felt he had a right to his opinion, although it might differ, as in one case reported, from that of other physicians consulted, and he had been able to do a good deal for the unfortunate sufferer. He must still doubt, however, if we ought to interfere with cancer of the stomach. Finally, he would reiterate the position he had assumed in his paper of the essential necessity, on the part of the successful practitioner of surgery, in determining the proper course to pursue in situations of peculiar doubt and difficulty, of qualities of rare good sense and judgment, discrimination and experience.

Adjourned.

AN EPIGRAPH "ON A QUACK."

"I was a quack, and there are men who say
That in my time I physick'd lives away;
And that at length I by myself was slain
With my own drugs, ta'en to relieve my pain.
The truth is, being troubled with a cough,
I, like a fool, consulted Dr. Gough,
Who physick'd me to death at his own will,
Because he 's licensed by the state to kill:
Had I but wisely taken my own physic,
I never should have died of cold and 'tisick.
So all be warned, and when you catch a cold,
Go to my son, by whom my medicine 's sold."

Medical Times and Gazette.

Medical and Surgical Journal.

THURSDAY, JULY 28, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE DISPOSAL OF REFUSE MATTER BY CREMATION.

IN continuation of our remarks on the subject of cremation in the last number of the JOURNAL we wish to direct attention to an interesting and valuable report rendered to the sanitary committee of the Commissioners of Sewers of the City of London upon some new methods of disposing of all kinds of refuse by cremation. The report is drawn up by Dr. W. Sedgwick Saunders, who is medical officer of health and analyst for London, and includes extracts from the reports of the sanitary and streets committees upon the same subject.

A deputation from these two committees visited certain towns in the north of England, among others Leeds, Warrington, Bradford, and Manchester, in which a system of cremation for the disposal of refuse is already in successful operation. This system involves two propositions, namely:—

(1) The destruction by fire of everything combustible in house and trade refuse; (2) the separation of the vegetable from the animal and mineral matters, and its conversion into charcoal.

The first process is accomplished in an apparatus termed a destructor, the second in a furnace called a carbonizer.

The destructor as described in general terms by its inventor, Mr. Fryer, of Nottingham, is a form of furnace designed for the reduction by fire of substances that contain only a small proportion of combustible material. A destructor of six compartments will consume 13,104 tons of refuse in fifty-two weeks of six working days, and of the total mass delivered eighty per cent. is entirely consumed by the fire. The carbonizer is also the invention of Mr. Fryer. In this machine six tons of market refuse produce one ton of charcoal without cost for fuel, and this charcoal being equal to the ordinary commercial article readily sells for twenty shillings a ton.

In one of the places visited by the deputation it learned that the sanitary authorities had saved £5000 a year under the process of cremation, out of a previous outlay of £17,000 under the old system. In another district, with a population of 60,000, the visitors found that the whole business was conducted by five men employed at a cost of nine pounds per week, and that with this plant upwards of 1000 cart-loads of house refuse were treated.

From a careful inspection of the various processes

in active operation the deputation of the sanitary and streets committees of London came to the unanimous conclusion that the system of cremation of refuse, including animal (condemned meat), vegetable, and mineral matters, as already inaugurated in the towns visited by them, is sound in theory and desirable in practice; that it has already passed beyond the experimental stage; and that it offers enormous advantages upon sanitary grounds, and is not to be despised for its commercial results. These gentlemen report that they not only saw a work consisting of poisonous and disgusting elements dealt with, and satisfactorily disposed of, without nuisance of any kind, but learned that products having a marketable value can be, and are, produced without any infraction of true hygienic principles, whilst at the same time these may have the effect of materially reducing the expenses.

Dr. Saunders sees in cremation of refuse a new line of departure of singular promise, and recommends the adoption by the commissioners of sewers of London of the system as described in his report.

All engaged in the investigation share the opinion that the establishment of such a system in the city of London will effect an enormous saving in the charges now incurred under the existing régime.

If this is true as regards London, what might not be accomplished by the adoption of such a system in New York, and in other large cities on this continent? The adoption of some process similar to that described by Dr. Saunders is surely only a matter of time, and we hope the subject will be kept steadily before the public mind. This form of agitation has our hearty sympathies, and as regards refuse we are willing to be classed with the Nihilists.

TOY PISTOLS AND THE DAILY PRESS.

THE daily papers have contained numerous items in regard to the many accidents following the use of miniature pistols. Apparently such accidents have been very frequent of late, and certainly in Baltimore they have been followed by an unusual mortality, twenty-three deaths due to a subsequent tetanus having occurred up to the present writing, if we can rely upon apparently authentic reports. The newspapers have very wisely taken occasion to preach sermons upon the impropriety of teaching the infant mind how to shoot with actual powder. Although the weapon is furnished only with a blank cartridge, the pasteboard wadding is able to penetrate the skin, and makes a sufficiently ugly wound to enable the toy to be classed as highly dangerous, as the writer has personally witnessed; and we heartily sympathize with all attempts to banish the murderous plaything. But while we gladly coöperate in all legitimate methods of attaining such a result, and have only praise for all legitimate newspaper enterprise, we cannot think that the object sanctions even the slightest departure from truth. The following item from the *Boston Journal* of July 20th has been especially brought to our notice:—

“Reports of the deadly effects of the toy pistols so

popular with boys on the Fourth of July continue to come in from all sections of the country. Boston has not been free from their devastations, several fatal cases of lockjaw being reported as the direct result of wounds in the hand which they have inflicted. The trade in these toy pistols seems to be responsible for almost as many deaths as are caused by the sale of weapons whose distinct purpose is to kill."

This statement was so startling in view of the very rare appearance of tetanus in this locality, that it seemed proper to make inquiries into the matter. By the records of the Board of Health there had been, from the 4th of July up to noon of the 20th, when inquiry was made, not one single death that in any way confirmed the statement of the *Journal*. Such carelessness in regard to facts is greatly to be regretted, and if ever the *Journal* moralizes on the influence of the daily press, that great educator of the people, may it add a single observation on the duty of the press to publish facts and not fancies, and at least to make sure of one death before it prints a wholesale obituary.

"METHOD IN MADNESS."

NOTWITHSTANDING its length we reproduce entire an editorial from the *Lancet*, with the above title. The attempted assassination of our president and the last murder in an English railway carriage have furnished the writer the text upon which to base his remarks. These we heartily commend to the perusal of our readers, not merely because the views expressed coincide with and support those advanced in the issue of the JOURNAL for July 14th, in an editorial upon the crime at Washington and its lessons, but mainly because in the two articles may be found an indication of the stand-point from which the best professional thought on both sides of the Atlantic is discussing some very delicate and difficult problems nearly affecting the happiness and welfare of society. The profession at large is even now not far behind its most enlightened and liberal specialists in its manner of regarding the relations between crime and insanity, but there are many among the laity — and those not the least intelligent and philanthropic — who will find themselves changing very greatly their present ideas, to which the word crude does scant justice.

Time and again since the shooting at Washington various daily journals have proved to their own entire satisfaction, and perhaps to that of their readers, that the assassin could not possibly be insane, because, according to his own confessions as well as the testimony of others, he could plan, and plot, and calculate, and even wait. Such observations seem also to have sufficed to settle the whole question for men having enjoyed the advantages of legal training and perhaps connected with official positions. The legal profession and the public would probably be most persuaded by a hard and fast definition of insanity. As such has not yet been framed in a manner to withstand criticism, and is not likely to be, each case must be investigated on its own merits, and there will be room for

mistakes, for ignorance, and for humbug. For all that, the discrimination between crime and insanity in their various proportions, and the methods of dealing with the different phases of both as they act and counteract upon each other, are sure to become more precise, and at the same time more humane and more protective to society.

MEDICAL NOTES.

— Under the head A Centennial Celebration, the *British Medical Journal* expresses a gratifying appreciation of the number of the JOURNAL published in honor of the centenary of the Massachusetts Medical Society.

"There is probably only one medical society in America which is in a position to celebrate its centennial anniversary. This is the Massachusetts Medical Society, which has just entered upon the second century of its existence, having been incorporated on the 1st of November, 1781. In honor of this event, the Boston Medical and Surgical Journal has published a special number devoted to centennial recollections and documents relating to the foundation of the Massachusetts Medical Society, including fac-simile letters, summaries, portraits, and other medical documents of the last century relating to the history of the society. Among others is a fac-simile of a certificate of fumigation after small-pox in 1776. It runs thus: 'These Certify that Eabenesor Stimpson has been so smook'd and eleane'd as that in our Opinion he may be permitted to pass into the Country without Danger of communicating the Smallpox to any one.' The number is one which is of great interest, and does credit to the patriotism and culture of our American colleagues. The Boston Medical and Surgical Journal is itself an excellent type of much that is most commendable and respectable in journalism — reserved, accurate, polished in form, and carefully noting all that is most promising and trustworthy in contemporary research. Its pages can never be consulted without profit and satisfaction."

— For the sake of simplicity and concentration the title page of the JOURNAL no longer exhibits the names of members of its editorial staff, but its readers still profit by the valued contributions of the JOURNAL's old representatives in New York and Philadelphia, Drs. P. Brynberg Porter and Frank Woodbury.

— Two hundred and sixty deaths from sun-stroke and 150 from excessive heat were reported in Cincinnati for the week ending July 16th. The total deaths for the week were 583, the average of total weekly deaths being about 115.

— According to late advices the number of medical men from outside Great Britain announced to attend the International Medical Congress in London was about 800. The aggregate attendance is expected to reach 2000. Earl Granville, foreign secretary, holds a reception of the foreign members on the 6th of August.

— The expenses of the congress are expected to reach \$30,000.

— Milk is insufficiently used in making simple puddings of such farinaceous foods as rice, tapioca, and sago. Distaste for these is engendered very often, I believe, because the milk is stinted in making them, or poor, skimmed milk is used. Abundance of new milk should be employed, and more milk, or cream, should be added when they are taken. In Scottish households this matter is well understood, and a distinct pudding-plate, like a small soup-plate, is used for this course. The dry messes commonly served as milky puddings in England are exactly fitted to create disgust for what should be a most excellent and delicious part of a wholesome dinner for both children and adults. — *Dr. Dyce Duckworth, in Popular Science Monthly for August.*

— In the sudden death of Dr. Maurice Raynaud (it is said, from angina pectoris) another has to be added to the great number of such occurrences that have told so disastrously of late on the profession in France, in the persons of Lorain, Chauffard, Broca, Delpsch, and Peisse. Although of late suffering much at times from overwork, Dr. Raynaud furnished no indication of approaching danger, and had recently been more than usually cheerful, in consequence of his having been selected to deliver the French address at the approaching Medical Congress. Indeed, he was playing with his children three hours before his death. Scarcely fifty years of age, he commenced his medical career by the production of a thesis, *Les Médecins du Temps de Molière*, which attained great popularity. He was an indefatigable worker, both at his profession and in literature, and at the time of his death last week was physician at La Charité, Agrégé of the Faculty of Medicine, member of the Section of Medical Pathology of the Academy of Medicine, and Officer of the Legion of Honor. Possessed of great oratorical power, much was anticipated from the address he was commissioned to deliver. — *Medical Times and Gazette.*

— The deaths from diarrhical diseases in Boston for the week ending July 25d were forty-two, as against fourteen for the preceding week.

— Ready method of preparing fomentations. Take your flannel, folded to the required thickness and size, dampened quite perceptibly with water, but not enough to drip, and place it between the folds of a large newspaper, having the edges of the paper lap well over the cloth, so as to give no vent to the steam. Thus prepared, lay it on the heated surface of the stove or register, and in a moment steam is generated from the under surface, and has permeated the whole cloth sufficiently to heat it to the required temperature. This method is often very convenient and efficient where there is no opportunity to heat much water at a time. — *Michigan Medical News.*

— In connection with the paper of Dr. Monat on Hospitals, the *Lancet* announces that it intends to publish on the 10th of July The Lancet Map of Medical London in 1881, showing the exact position within the metropolitan area of the metropolis of every hospital in it. This map has been prepared with considerable care, and will show foreign guests the resources at present

at command in dealing in medical institutions with the indoor treatment of disease and accidents in the largest city in the world. The information conveyed by it, aided by an explanatory index, will tend to show the urgent need which exists of some redistribution of the medical relief of the poor of London and its surroundings.

NEW YORK.

— The governor of the State has vetoed the bill providing for the construction of another aqueduct for the purpose of increasing the water supply of New York, on the ground that the present supply, if properly husbanded, is sufficient, and the outlay required for the purpose would therefore be a waste of money. There is, unfortunately, reason to believe that this action on the part of the governor is to be attributed to political expediency rather than to an honest regard for the public welfare, and it is greatly to be regretted because there can be no doubt that, notwithstanding the greatest possible economy that could be practiced in the use of the present water supply, there would be urgent need for an increase by the time that so extensive a work as the construction of a second and larger Croton aqueduct could be completed.

— As usual at this season of the year, the infant mortality in the city is exceedingly large, and with a view of reducing this as much as possible the annual temporary corps of fifty physicians has been appointed, and is now engaged in making house-to-house visitations in all the tenement districts of the city, for the purpose of caring for all sick and feeble children not under medical attendance. With the same end in view the various sea-side sanatoria have been opened, and the excursions of the St. John's Guild Floating Hospital are being made several times each week, as usual in July and August.

— The Citizens' Committee of Twenty-One have just published, in pamphlet form, their report in regard to the late street-cleaning agitation. In the course of it they refer to the law that was finally passed by the legislature as follows: "It is a radically defective legislative compromise, to which the Committee of Twenty-One is not a party, and the responsibility for which it does not assume; it is obviously a measure originating in a desire to appease popular indignation, and to escape popular reprehension by an apparent concession to the demand of the people for some change in the system of street-cleaning." In conclusion the report states that the work of the committee is not yet completed, and that its organization will be continued, because legislation will be required at the next session to complete and perfect the details of the new plan, if it is found on the whole to be sufficient, or if it is not so found to procure another and a better law. "Certain trading politicians," it goes on to say, "are relying upon the public becoming apathetic and indifferent on the subject, and being satisfied with half-way concessions. They count upon the proverbially short memory of grievances of the citizens of New York. The committee proposes not to let the subject be forgotten

so long as there is occasion to preserve its remembrance."

— An ordinance has been passed by the board of aldermen and approved by the mayor which makes it a misdemeanor to throw banana skins and other similar substances on the sidewalks, and requires all dealers in fruit and vegetables to have copies of the ordinance conspicuously posted about their places of business, so that their customers may become aware of its provisions. The law was first proposed some time ago by an alderman who saw a woman slip on a banana skin in the street and fall with such violence that she broke her leg.

— An infant, six months old, recently died of an overdose of opium through a druggist's mistake. The physician who was attending the child ordered seven powders containing opium for it, but the druggist who put up the prescription divided the quantity of the drug specified into only two powders.

— An exceptionally large number of New York physicians have gone abroad this summer, and most of them will attend the sessions of the International Medical Congress in London.

Miscellany.

SOME CRITICISMS ON A PAPER READ BY DR. PELTZ BEFORE THE PHILADELPHIA MEDICO-LEGAL SOCIETY.

MR. EDITOR, — In the issue of the JOURNAL for June 30th, an account is given, in a letter from Philadelphia, of a new departure in the practice of medicine advocated by Dr. Peltz, of that city, in a paper read before the Philadelphia Medico-Legal Society. He advises physicians, in view of "the adulterations and substitutions practiced by druggists, and their extortionate prices," to prepare their own prescriptions. An earnest protest on the part of the pharmacists is certainly not uncalled for. A grave and sweeping charge of unprofessional conduct is made against them as a body, — a charge which is galling in the extreme to a class of men having a natural pride in their profession, and an earnest desire to advance its usefulness and honor.

In the general defence of pharmacy I do not feel called upon to speak. "There she stands." I cannot do better than refer you to the learned volumes which contain the annual reports of the American Pharmaceutical Association. Moreover, if the profession have fallen from their high standard the burden of proof is on their accuser, and he has not sustained it by the isolated instances which he has given, even supposing them all well founded. It is unjust to insinuate that these petty exceptions are the rule. If a profession is to be annihilated for the sins of its worst members, where, I respectfully ask, would the doctors be?

Against no body of men could the charges of Dr. Peltz's article be brought with less foundation than against the pharmacists of Philadelphia. In their high standing in their profession, in the contributions which they have made to pharmaceutical and medical science, — in everything, in fact, but the alleged "self-interest and want of principle," — they stand preëminent. Among the many eminent names which adorn their rolls, let me mention particularly those of Maisch,

Remington, Proctor, Shinn, Taylor, and the late lamented Parrish. It was through the exertions of Philadelphia druggists that an act was passed by the legislature in 1872, part of which I quote in order to show the security afforded to physicians and to the public against inexperience on the part of pharmacists. After providing for the examination and registration of all persons who propose to keep drug stores, or to put up prescriptions, it continues as follows: —

"Sec. 8. No person not a graduate in pharmacy shall be allowed by the proprietor or manager of any store to compound or dispense the prescriptions of physicians (except as an aid under the immediate supervision of said proprietor or his qualified assistant) unless he has been at least two years apprenticed in a store where medicines are compounded and dispensed, and has attended one full course of lectures on chemistry, materia medica, and pharmacy; and no proprietor shall leave his store in charge of any but a qualified assistant." . . .

Section 10 is especially worthy of Dr. Peltz's attention, for it provides in substance that any person who shall knowingly falsify or adulterate any drug or medicinal substance, or any preparation authorized or recognized by the Pharmacopœia of the United States, or used or intended to be used in medical practice, and shall sell the same for medicinal purposes, shall be guilty of a misdemeanor, and, upon conviction thereof, shall pay a penalty not exceeding five hundred dollars, and shall forfeit to the commonwealth all of the articles so adulterated.

Dr. Peltz implies that pharmacists are an unnecessary class, rather an obstruction to the public health than otherwise, and that physicians can with the utmost ease do for themselves what the pharmacists now do for them. This, I venture to say, is a serious mistake. It is no disparagement to the noble profession of medicine to say that the carpenter is not a more necessary ally of the architect than is the pharmacist of the physician. Centuries ago, indeed, when medicine was in its infancy, one man might learn all that was then known; but in the vast progress of scientific knowledge the study has long since resolved itself into a group of learned professions, any one of which demands the devoted study of a lifetime. That of the physician is one, and that of the pharmacist is another. I protest against the introduction of a combination, the result of which can be neither good physicians nor good pharmacists, but inferior "medico-pharmacists."

The long history of the pharmaceutical profession in the western world from the revival of learning after the dark ages down to the present day, when it is better organized and equipped than ever before, more watchful and solicitous than ever for the public health, is in itself the best argument for the necessity of its existence. It has gained, so to speak, a "prescriptive" right to live. No "irrepressible conflict" does or can exist between the two professions. They can be neither rivals nor enemies, but only allies. It is the part of the physician to watch the symptoms, to locate the disease, to prescribe and administer the remedy. It is for the pharmacist, acting in this respect as the *responsible agent* of the physician, to furnish the materials in the form prescribed.

Has the advocate of the novel scheme of reform considered the difficulties in the way of its adoption? Besides the elaborate and costly apparatus with which every respectable pharmaceutical establishment is fur-

nished, there must be kept on hand some five hundred kinds of herbs, and drugs and chemicals, tinctures and elixirs without number. Now if a physician undertakes to put up his own prescriptions he too must keep on hand all these various materials, for any of them may be needed at any moment. And yet many of them will lie on his shelves months and years unused. Corruption and deterioration inevitably result, unless new drugs are bought at frequent intervals and the old thrown away, which involves ruinous expense. The pharmacist's stock, on the other hand, is always changing, and therefore likely to be always pure.

Again, supposing the physician to have procured the drugs and apparatus, can he, amid the engrossing duties of his own profession, acquire the skill in manipulation, the knowledge of chemical effects, the delicacy of taste and smell, and keen perception of shades of color which enable the trained pharmacist to detect almost imperceptible traces of impurity, and to distinguish between the deadly poison and the harmless drug, which to the unpracticed eye appear identical?

Another obstacle — perhaps the most insuperable of all, as the author of the innovation will discover as his practice increases — is the waste of valuable time involved. A physician with an extensive practice cannot attend to his patients and his prescriptions too.

The charge of extortionate prices brought against pharmacists — and physicians — by persons who undervalue experience and skill, reminds one of the story of the darkey who grumbled because a doctor had charged him twenty dollars for cutting off his leg. "Why, Sambo," said a more philosophic friend, "De gen'l'man did n't charge you but five dollars for de sawin'; de fifteen dollars was for de *know how*."

The public should take into account the long and weary years spent by the pharmacist in acquiring his skill, and the grave responsibilities attending his business. Few of them acquire a competency, for theirs is a profession poorly paid, except by the respect of the community and the consciousness of good work faithfully done.

PHARMACIST.

ALUMNI ASSOCIATION OF THE ALBANY MEDICAL COLLEGE.

THE attention of the alumni of the Albany Medical College is called to the following announcement: —

At a meeting of the executive committee of the alumni, held June 16, 1881, the president stated that he had given considerable thought to the matter of prize essays to increase the interest in and efficiency of the association. He had concluded to offer an annual prize of one hundred dollars, to be called "a surgical prize," and would announce as the subject for an essay this year, Colles's Fracture, its Pathology and Treatment, the paper to be accompanied either by a pathological specimen illustrating the fracture, with or without dislocation of the ulna, or by a careful dissection of the hand, wrist, or forearm.

After favorable remarks by members of the committee, on motion of Dr. L. Hale, Dr. Van Derveer, the president, was appointed a committee of one to give the matter further consideration. Subsequently the president reported that the heirs of the late Prof. Alden March, M. D., LL. D., desired to give the sum of one hundred dollars as an annual "March Memorial Prize," the essay for the coming year to be on the Pathology and Treatment of Morbus Coxarius. Also,

that Mr. McClure, a governor of the Albany Hospital, had decided to give the sum of one hundred dollars annually as an "Armsby Memorial Prize," the essay to be on some anatomical subject. That for the coming year will consist of a minute description of the genito-urinary organs of the male, together with a carefully dissected specimen of the same. The president further reported that the heirs of the late Prof. James MacNaughton, M. D., had offered the sum of one hundred dollars as a "MacNaughton Memorial Prize," the subject of the essay for the current year to be Antisepsis in the Treatment of Diseases.

Mr. Joseph Russell, a trustee of the college, offers for this year a second surgical prize of fifty dollars for the second best essay on Colles's Fracture.

Essays and specimens designated by a motto, and accompanied by a sealed envelope, inclosing the name and address of the author, must be sent to the secretary of the association, Dr. W. G. Tucker, by the 14th day of February, 1882.

The committee to examine the essays for this year will consist of Drs. A. Van Derveer, J. S. Mosher, and Lorenzo Hale, and they reserve the right to reject any or all essays if not deemed worthy.

All specimens are to be deposited in the new museum of the college, properly labeled.

TREATMENT OF THE INSANE.

MR. EDITOR, — Your recent editorial on *The Crime at Washington* and its Lessons, which so well reflects the opinions of specialists if not of the whole profession, reminds me that the subject of the treatment of the criminal insane was under discussion at the last meeting of superintendents at Toronto. It has often been discussed in that body, and the opinion has always been in favor of separate treatment for this class. Certain practical difficulties have, however, always presented themselves. The result of this year's discussion was the appointment of a committee of three, consisting of Dr. Gundry, of Maryland, Dr. Fauntleroy, of Virginia, and Dr. Fisher, of Massachusetts. The committee are to consider the advisability of separate provision for idiots and imbeciles, for epileptics, dipsomaniacs, and the criminal insane. As a member of that committee I would ask for contributions of pamphlets, documents, or statistics bearing on these subjects. I am yours very truly, THEO. W. FISHER.

THE INTERNATIONAL MEDICAL CONGRESS.

THE death of M. Raynaud, which we announced last week, has deprived the Congress of one of its orators, to listen to whom would have been one of the chief treats of a week which promises to be full of interest. M. Raynaud had acquired a great reputation as an orator, and the subject of his address, Skepticism in Medicine in the Past and Present, is one that in able hands must always prove attractive. M. Raynaud's death was quite sudden, and was caused by an attack of angina pectoris, from which he had suffered for some months. Fortunately, he has left the MS. of his address prepared for delivery. Under these circumstances it would be an appropriate mark of respect to have it read by one of his friends, and for this task, honorable but painful, no man is better qualified than

Dr. Guéneau de Mussy. Although it was doubtful if Professor Virchow would be able to attend the Congress, he has, as we stated last week, at length expressed his intention to be present, and, at the request of the Executive, to give an address on "The Bearing of Pathological Experiments on Medicine." The date fixed for Professor Virchow's address is Thursday, August 4th. There is no name more famous in natural science than that of Rudolph Virchow; no man has exerted a greater influence upon the scientific teaching of his day, and his presence and active participation in the work of the Congress will greatly add to the *éclat* and success of the forthcoming meeting.

While the general arrangements for the Congress are such as to command general approval, it is a matter of great regret that Sir William Jenner will not be able to take a more prominent part in the scientific work of the meeting. No one in the profession commands a more hearty, complete, and universal confidence, whether we regard him as a man of science, as a practitioner of his art, as a teacher, or as a rigid upholder of the honor and dignity of the profession. According to present arrangements Sir William Jenner will preside at the first general meeting of the Congress, and will deliver the address of welcome. He will thus take a prominent position in the formal work of the Congress, which will be gladly welcomed by all his brethren. We still, however, cherish the hope that he will be able at some one of the meetings to give a scientific address, either on the clinical study of medicine or on some kindred subject. A scientific contribution from one who without question ranks as the head of the profession in Great Britain will go far to make this great meeting of medical men from all parts of the world in our metropolis a success. A resolution formally opening the Congress will be moved by Sir Risdon Bennett and seconded by Professor Donders at the first general meeting, after Sir William Jenner's address.

A suggestion has been made that on one of the evenings a fête should be given at the Botanical Society's Gardens. Many obstacles, however, presented themselves to the successful carrying out of this plan, and the executive committee has finally abandoned the idea. Surely the programme is full enough already! Three evenings will be occupied with receptions or fêtes, and those that are not so filled up will not be too many for the exercise of private hospitality, or for the unrivaled attractions of London society. His Royal Highness the Prince of Wales takes great interest in the success of the meeting, and has not only promised to attend the opening meeting of the Congress, but has accepted an invitation to lunch afterwards with Sir James Paget, and to dine in the evening with Sir William Gull, who is asking the Vice-Presidents and Council of the Medical Section, the Presidents of the other sections, and some distinguished foreign visitors to meet His Royal Highness. The Prince has also signified his intention of being present at the reception at the South Kensington Museum the same evening, to which it is hoped the Princess will accompany him. Every member of the Congress will be entitled to take one lady to the soirée at South Kensington Museum; the members only are asked to the College of Surgeons.

The entertainment by the Corporation of the City of London will be given on Friday, August 5th, and the reception at the College of Surgeons will be postponed to Monday, August 8th. An announcement has been

made of the sum of money voted by the corporation for its soirée, but the hospitality of the city is so well known that we need no assurance of such kind that it will be on a magnificent scale. The old hall itself, and still more the museum and library, are of considerable interest, while the pageantry of the City Court is such as to excite the curiosity of more than our foreign guests. Two thousand cards of invitation have been placed at the disposal of the reception committee of the Congress, a certain number of which are for ladies, and the corporation has reserved 1000 cards for its own use. The programme of proceedings contains, in addition to these, a long list of entertainments, to which only a limited number is invited. Although a book is kept at the College of Physicians for the purpose of recording the names of those desirous of joining these parties, we would remind our readers that the ultimate nomination for invitation will rest with the reception committee. They will have a difficult duty, and it behooves every one loyally to support them in their decisions. The barest hospitality renders it absolutely essential that our foreign friends should have every facility afforded them of enjoying the entertainments provided on this occasion. It is of all occasions one specially unsuited for a display of selfishness, which, if indulged in, would leave an unfavorable impression that will take years to erase.

Nearly 1800 medical men have notified their intention of attending the Congress, and about 500 have already paid their subscriptions. Medical students will be admitted to the business meetings of the Congress on the payment of an entrance fee of 10s. 6d.

The following distinguished foreigners have accepted the position of honorary vice-presidents of the Congress: Professors Donders, Brown-Séquard, Kolliker, Ollier, Pflüger, O. Liebreich, Looen, Chauveau, Hardy, Holmgren, Tarnier, Baccelli, Verneuil, Santesson, Goltz, Pasteur, Tilanus, Virchow, Billings.

At a special general meeting of the Medical Society of London, to be held on Monday next, the following gentlemen will be proposed for election as Honorary Fellows in connection with the Congress: Professor Bamberger, Dr. G. H. Billings, Dr. Bigelow, Professor Billroth, Professor Chareot, Professor Da Costa, Dr. Emmet, Professors Haller, Nussbaum, Tarnier, Verneuil, and Volkmann. — *Lancet*.

METHOD IN MADNESS.

No psychologist has hitherto been able, and probably it is impossible, to define *madness*, or to give a clearly marked indication of the boundary line between sanity and insanity. Mental soundness is merged in unsoundness by degrees of decadence which are so small as to be practically inappreciable. It is with the mind-state which precedes the development of a recognized form of insanity the therapist and the social philosopher are chiefly interested. Although in individual cases the subject of mental derangement may, as the phrase runs, "go mad" suddenly, speaking generally, insanity is a symptom occurring in the course of disease, and commonly not until the malady of which it is the expression has made some progress. Those mental disturbances which consist in a temporary aberration of brain function, and which are the accidents of instability, rather than the effects of developed or even developing neuroses,

can scarcely be classed as insanity, although it is true, and in an important sense, that these passing storms of excitement or spells of moody depression may — acting reflexly on the cerebral and nervous centres, as all mind-states and mind-movements react — exert a morbid influence, and lay the physical bases of mental disease. The consideration most practical to the community and germane to the question of public safety is that in any and every population there must exist a dangerously large proportion of persons who are always in a condition of mind to be injuriously influenced by any force which powerfully affects them. As a matter of history, it would seem that the majority of such persons are controlled rather than morbidly excited by the opportunity of throwing themselves into any popular movement. They may suffer afterwards for the stimulation they receive at the time of public commotions, but while these are in progress they link their own consciousness with that of other minds, and the tendency to develop individual eccentricities of mental action is thereby for the moment repressed or exhausted. It is in the intervals of great public excitement the peace is disturbed by the vagaries of criminals who are more or less reasonably suspected of being "insane."

It would be premature to assume that the murderer of Mr. Gold, or the man who attempted to assassinate the President of the United States of America, was insane. There are circumstances in connection with each of these tragedies which must suggest the reflection that the assailants were possibly, or even probably, of unsound mind. We do not, however, propose to discuss these features of the respective cases at this juncture. The full facts are not, as yet, ascertained; but enough is known to warrant an endeavor to clear the way for future remark by disposing of the objection that the suspected perpetrator of the Brighton outrage and the would-be assassin of the President both showed "forethought" and "method." It is a common formula for the expression of doubt as to the irresponsibility of an alleged lunatic that there is "method in his madness." Nothing can be farther from the truth than the inference to which this observation is intended to point. It is not in the least degree necessary that a madman should be unconscious of the act he performs, or of its nature as a violation of the law of God or man; nor is it necessary that he should do the deed under an ungovernable impulse, or at the supposed bidding of God or devil, angel or fiend. The forms of mental disease to which these presumptions apply are coarse developments of insanity. Dr. Prichard was among the first of English medico-psychologists to recognize the existence of a more subtle form of disease, which he termed "moral insanity." Herbert Spencer supplied the key-note to this mystery of madness when he propounded the doctrine of "disorganization;" and Dr. Hughlings Jackson has since applied that hypothesis to the elucidation of morbid mental states and their correlated phenomena. When disorganizing — or, if we may borrow an expression from the terminology of geological science, *denuding* — disease attacks the mental organism, it, so to say, strips off, layer by layer, the successive strata of "habit," "principle," and "nature," which compose the character. First in order go the higher moral qualities of the mind, next those which are the result of partially formed habits, then the inherited principles of personal and social life. At length the polish

which civilization gives to humanity is lost, and in the process of denudation the evolutionary elements of man's nature are progressively destroyed, until he is reduced to the level of a creature inspired by purely animal passions, and obeying the lower brutish instincts. The term "moral insanity" is accurate as far as it goes, but it expresses only the first stage in a process of dissolution which is essentially the same throughout, but which has unfortunately received different designations as its several features have been recognized and studied apart. The difference between the subject of "moral insanity" and the general paralytic, who has lost all sense of decency and lives the life of a beast, is one of degree. The practical difficulty is to convince the mere observer that forms of insanity which seem to consist in the loss of moral qualities and principles *only* may be as directly the effect of brain disease as any of those grosser varieties of mental disorder which he is perfectly well able to recognize, and fully prepared to ascribe to their proper cause.

To the professional mind, at least, it will follow from what we have said that the injury to mind properties or qualities inflicted by the invasion of disease may be partial, and must in every case be determined by laws or conditions governing the progress of disease, perhaps on the lines and in the directions which have been least well guarded by educational influences. A man may lose his faculty of forming a wise judgment long before he is deprived of the power of distinguishing between right and wrong. This is so because it is a higher attainment in moral culture to do right advisedly than simply to perceive the right thing to do. The application of principle to conduct is an advance on the mere recognition of virtue in the concrete; or even the possession of virtue in the abstract. The question whether any past act of wrong-doing was an act of insanity does not so much depend upon the great question whether the person doing it was insane as a whole being, as whether the deed done was the outcome of passion or error, the direct fruit of limited or special disease. In short, the insanity of the act must be inferred from the morbid condition of the brain from which it sprang, rather than from the act itself. A partially disorganized — or, as we prefer to say, "denuded" — brain may be fully capable of sane thought, except on some one topic, and able to exercise every intellectual function except of a particular order. Or there may be mental weakness and neurotic susceptibility in regard to a special class of impressions. It would be difficult to name any form of act or submission which may not be the outcome of incipient or limited disease. The practical difficulty is to avoid, on the one hand, treating the fruits of disease as willful offenses; while, on the other, we do not allow the supposition or presumption of disease to be employed as an excuse for wrong-doing. It is of course clear that there may be perfect method in such madness as springs from partial or commencing brain disease; for every element in the mental process which culminates in a mad act may be sane except the inception of the idea in which the act took its rise. Thus, in the case of the suspected murderer of Mr. Gold, there may have been perfect sanity in respect to every stage of the process by which the crime was planned and carried out, and yet insanity, the effect of brain disease, in the idea by which the deed was suggested. For example, when a man is suffering from morbid suspicion, and, fixing his distrust on some

individual, purposes to murder him, the intellectual processes by which he lays his plans and fulfills his morbidly conceived intention are performed with perfect sanity, as by a sane will. It is important to recognize this. There is no difference in *nature* between the mental operation by which a "sane" man contrives and executes a crime and that by which a known "lunatic" will commit the like offence. There may be as much *method* in the one instance as in the other, and the faculties which exhibit this method may be as sound and effective, but in the one case the idea behind the act is sane, while in the other it is insane. The brain is not one large homogeneous organ, to be healthy or diseased, orderly or deranged, throughout at any one period. Inflammations, and diseases generally, which affect the brain as a whole do not commonly cause insanity, properly so called. The organ of the mind is a composite or aggregate of cells or molecules, any number or series of which may be affected with disease while the rest remain healthy. At present we are only on the threshold of investigation concerning the physical causes of insanity, and have scarcely done more than recognize the possibility of *molecular* disease of the brain. Hereafter science will probably succeed in unveiling the obscure facts of molecular brain pathology, and enable the medical psychologist to predicate disease of recog-

nized classes of brain elements from the special phenomena of mind disturbance. This is the line of inquiry and the result to which the progress already made distinctly tends.

For the present, the inferences we can surely draw from known facts are very few; but prominent among the number are certain which it is all-important to recognize in view of the judgment which must hereafter be formed on the two cases now engaging public attention on both sides of the Atlantic. The existence of method in madness is no marvel, and that characteristic cannot therefore be supposed, or alleged, to weigh as evidence against the "insanity" of the criminal. The perpetrators of these heinous offenses against common right and public safety may be more or less responsible for their acts, and, so far as these are concerned, more or less sane or insane. The measure of the morbid element in their individual cases will be the health or disease of the particular part or element of the brain from which the offense sprang. The ultimate judgment formed must be determined upon the basis of scientific tests to be applied to the action of the brain alleged to be the subject of partial or incipient disease. There is nothing in the facts as they stand to supply the materials for a judgment. Precise scientific inquiry can alone solve the enigma each case presents. — *Lancet*.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 16, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 4230 (no return from St. Louis or New Haven); 2339 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 1646, diarrheal diseases 1209, consumption 366, lung diseases 153, diphtheria and croup 136, scarlet fever 88, small-pox 47, typhoid fever 38, malarial fevers 38, cerebro-spinal meningitis 29, whooping-cough 24, measles 15, puerperal fever 15, erysipelas four, typhus fever three. From *small-pox*, Chicago 15, Philadelphia 14, Pittsburgh 10, Brooklyn and Westfield one. From *typhoid fever*, New York eight, Pittsburgh seven, Philadelphia and Chicago four, Boston three, Baltimore, New Orleans, Buffalo, and Charleston two, Milwaukee, Nashville, Lowell, and Lawrence one. From *malarial fevers*, New York 10, Brooklyn nine, New Orleans seven, District of Columbia five, Baltimore and Charleston two, Chicago, Buffalo, and Nashville one. From *cerebro-spinal meningitis*, New York 12, Chicago eight, Philadelphia four, Fall River two, Boston, Charleston, and Marblehead one. From *whooping-cough*, Philadelphia five, New York and Providence four, Baltimore and Buffalo three, Brooklyn, Chicago, Pittsburgh, Milwaukee, and Malden one. From *measles*, New York six, Brooklyn and Providence two, Chicago, Pittsburgh, Buffalo, Milwaukee, and Nashville one. From *puerperal fever*, Boston four, Brooklyn and Chicago two, Pittsburgh, Buffalo, Milwaukee, Lowell, Fall River, Lynn, and New Bedford one. From *erysipelas*, New York three, Milwaukee one. From *typhus fever*, New York three.

Twenty-one cases of small-pox were reported in Brooklyn, 29 in Chicago, 53 in Pittsburgh, two in Milwaukee; diphtheria 32, scarlet fever three, in Boston; scarlet fever six, diphtheria three, in Milwaukee. Two hundred and sixty-four deaths from sunstroke and 150 from excessive heat were reported in Cincinnati.

In 41 cities and towns of Massachusetts, with a population of

1,086,643 (population of the State 1,783,086), the total death-rate for the week was 20.07, against 18.02 and 17.00 for the previous two weeks.

For the week ending June 25th in 149 German cities and towns, with an estimated population of 7,840,903, the death-rate was 26.4. Deaths reported 3985; 2079 under five; pulmonary consumption 503, acute diseases of the respiratory organs 296, diarrheal diseases 256, diphtheria and croup 112, scarlet fever 81, typhoid fever 57, measles and röteln 46, whooping-cough 29, puerperal fever 19, small-pox (Königsberg three, Lübeck, Berlin, Harburg, Aachen two) eight, typhus fever (Königsberg three, Bromberg) four. The death-rates ranged from 15.1 in Duisburg to 40.5 Breslau and Munich; Königsberg 32.8; Dresden 26.2; Berlin 32.3; Leipzig 16.5; Hamburg 23.6; Hanover 22; Bremen 24.1; Cologne 27.7; Frankfurt 20.1; Strasburg 39.2.

For the week ending July 2d in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 19.5. Deaths reported 2849: acute diseases of the respiratory organs (London) 181, diarrheal 130, measles 100, whooping-cough 91, scarlet fever 66, small-pox (London 52) 59, fever 28, diphtheria 24. The death-rates ranged from 13.2 in Plymouth to 25.1 in Liverpool; Sheffield 16.4; Birmingham 17.1; Manchester 18.7; Bristol 18.9; London 19.6; Leeds 21.2. In Edinburgh 19.6; Glasgow 23.7; Dublin 18.7.

In the 21 chief towns of Switzerland, for the week ending July 2d, population 479,934, there were 25 deaths from diarrheal diseases, acute diseases of the respiratory organs 18, measles seven, typhoid fever five, diphtheria and croup four, whooping-cough one. The death-rates were: Geneva 22.8; Zurich 26.4; Basle 20.1; Berne 19.9.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 16, 1881, TO JULY 22, 1881.

SIMONS, JAMES, lieutenant-colonel and surgeon. Granted leave of absence for one month. S. O. 129, A. G. O., July 15, 1881.

APPOINTMENTS AT THE BOSTON DISPENSARY. — A department of diseases of women has been established at the Boston Dispensary, to be under the charge of Drs. W. H. Baker, F. H. Davenport, C. M. Green, and J. W. Elliot.

Dr. G. M. Garland has been appointed physician at the central office.

Drs. G. H. Tilden, John B. Swift, J. W. Farlow, M. H. Prince, and L. W. Kyle have been appointed district physicians.

BOOKS AND PAMPHLETS RECEIVED. — May 1881. *Practical and Rational Treatment of the Diseases of the Skin*. By I. Edmonson Atkinson, M. D. (Reprint.)

On "Kerion Celsi," a Variety of Tinea Tonsurans. By I. Edmonson Atkinson, M. D. (Reprint.)

Considerations respecting the Mechanical Treatment of Hip Disease, with Special Reference to the Value of Traction. By A. B. Judson, M. D. (Reprint.)

Atlas of Skin Diseases. By Louis A. Duhring, M. D. Part IX. (Conclusion.) Philadelphia: J. B. Lippincott & Co. 1881. (A. Williams & Co.)

Fifth Annual Report of the State Board of Health of Wisconsin. 1880.

Dengue. By J. G. Thomas, M. D., Savannah, Ga. (Reprint.)

State Medicine. What has been Accomplished and What is Needed in Indiana. By Thaddeus M. Stevens, M. D. (Reprint.)

The Forty-Second Annual Report of the Superintendent of the Boston Lunatic Hospital to the Board of Directors of Public Institutions. For the Year ending April 30, 1881.

Quarterly Report of the Medical Officers of the United States Army, with their Stations and Duties, as reported to the Surgeon-General, July 1, 1881.

Lectures.

THE REFLEXES.

NOTES FROM ONE OF PROFESSOR ERB'S LECTURES
ON THE DIAGNOSIS OF DISEASES OF THE NERVOUS SYSTEM. LEIPZIG.

BY GEO. L. WALTON, M. D.

ALTHOUGH physiologists have busied themselves extensively with the study of reflex action in general, that branch of the subject which is of practical diagnostic value has been comparatively neglected. There is room for much valuable work even on the healthy subject, upon the reflex movements brought out by the stimulation of various parts of the body, and to the practical physician the subject is one of great importance.

The principal reflexes of diagnostic value are the skin, tendon, pupil, palate, and sphincter reflexes.

SKIN REFLEXES.

These are limited in health to certain parts of the body.

The reflex movement produced by tickling the *sole of the foot* is best seen in children and in "nervous" people. It varies greatly within normal limits, and with these variations it is necessary to become familiar before drawing diagnostic conclusions. This reflex is best tested by drawing the finger-nail or the handle of a percussion hammer quickly from toe to heel. The result, as seen on the healthy man used for illustration, is a contraction of the quadriceps extensor. A slight contraction appears also in the muscles on the front of the leg, so that the foot is flexed as well as drawn away. In the foot itself no reflex is seen. This is the only normal skin reflex about the foot, unless sometimes a slight contraction when the dorsal surface is pinched.

Cremaster reflex. On stroking the anterior and internal surface of the thigh, a contraction in the cremaster muscle is seen to follow, by which the testicle is elevated. In a similar manner the scrotal muscles contract when we pinch the skin of the scrotum. These contractions are under abnormal conditions much decreased, and are normally more marked in boys than in adults. In this boy, for instance, when the thigh is stroked the testicle is seen to ascend nearly to the inguinal ring.

The *abdominal reflex* is best tested with the patient lying down, as the abdominal muscles in the erect position are very tense. The abdomen should be unexpectedly stroked, and will immediately retract. This reflex is easily wearied by a few repetitions.

Mamillary reflex. In the normal subject, the nipple on being stroked becomes hard and elevated, that is, assumes a state of erection. At the same time the areola is drawn together.

Palpebral reflex is tested by approaching the eye quickly with the finger or by stroking the cilia. Under pathological conditions the conjunctiva may be touched to determine if palpebral reflex exist, though of course in health this stimulus is never necessary.

The foregoing are the only skin reflexes found in the normal subject. In disease they may be wanting on the one hand or increased on the other, and new skin reflexes may be developed.

TENDON REFLEX.

The value of the tendon reflex in diagnosis was discovered in 1876, since which time the literature on the subject has multiplied rapidly. This phenomenon is produced by the stimulation of certain tendons, for example, that of the quadriceps extensor femoris. That the reflex is produced by stimulation of the tendon and not of the skin is easily shown on animals by removing the skin over the tendon; on man by shoving the skin over the tendon to one side and stimulating it. This reflex appears in the healthy subject on stimulation of the tendon of the quadriceps femoris, of the triceps, and the tendo Achillis.

Patellar tendon reflex. This is by no means easy to demonstrate in all cases in which it exists. The knee of the leg to be tested is crossed over that of the other, and the leg allowed to hang down with no muscular effort on the part of the patient. This position is preferable to the recumbent, for in the latter position the tendon is relaxed, the reflex being in all cases best obtained when the tendon is slightly stretched. A short, sharp, light stroke is given with a percussion hammer on the tendon, just below the edge of the patella. The result in health is a contraction of the quadriceps muscle. The great difficulty to contend against is involuntary muscular effort on the part of the patient.

The phenomenon is in health almost constant, but as it is wanting in one and one half to two per cent. of normal subjects, its absence cannot be taken for an absolute sign of disease, which is an important fact to bear in mind.

The patellar reflex may be in disease increased to such a degree that the least touch calls out a series of clonic contractions, or it may, on the other hand, be entirely wanting. It is wanting in tabes dorsalis, for example, and in atrophic paralyses, either of peripheral or of spinal origin. It is generally increased in cases of spinal lesion in the dorsal region.

Reflex of the *tendo Achillis* is tested as follows: The foot is held at a right angle to the leg in order that the tendon may be slightly stretched. The tendon is then struck lightly about two and one half finger breadths above the apex of the heel. A slight extension of the foot results in the normal subject. About the lower extremities there are no more normal tendon reflexes, except sometimes a slight contraction of the adductors on striking the inner surface of the thigh.

Triceps reflex. This is called out by striking the tendon just above the elbow, the arm being held in a position of flexion.

A slight reflex may be sometimes found in the biceps and in the wrist flexors on striking their respective tendons. These reflexes are, however, very inconstant in health. In disease they may be very marked.

Here is a patient with an organic central lesion. He has a spastic gait, his legs are stiff, and he almost hops on his toes. In a patient with this gait we generally find exaggerated reflexes. On attempting to bend his knee we find a powerful resistance, due to involuntary muscular contraction.

We find an immense reflex following the slightest stroke on the tendon, not only below the patella but even above it, over a triangular space which represents the spreading of the tendon. This reflex is in some cases so much exaggerated that one stroke is followed by a series of clonic contractions.

In such a case as this one the reflex of the tendo Achillis is best tested by holding the foot in the hand with the thumb to the dorsum of the foot. The foot is now bent with a quick jerk towards the knee, and pressed firmly, though not too forcibly, upward. The result is a series of contractions, each relaxation being followed by a fresh stimulus as long as the foot is held firmly upwards. The fact that this stimulus is enough to keep up the reflex is in itself evidence of a pathological condition. This phenomenon is in some cases best demonstrated by holding the foot in a position of abduction, in others of adduction. The phenomenon is almost never to be produced in health, though in persons with weak nerves two or three contractions may follow. When, therefore, as in this case, a distinct series of contractions follow, a pathological state is almost surely diagnosed, probably an organic lesion in the cord or brain.

As we proceed in the examination of the case before us we find that striking the inner surface of one thigh calls out contractions in the adductors of both thighs. A reflex also follows stimulation of the tendo tibialis postici as it passes the inner malleolus, also of the peroneal tendons as they pass under the outer malleolus, also that of the tibialis anticus as it passes over the ankle. Reflexes from the biceps and from the wrist flexors are marked. In this patient the plantar, abdominal, and mamillary reflexes are well shown.

The number of muscles exhibiting the reflex phenomenon may be in pathological cases much increased, the deltoid, the scapular, and the dorsal muscles, for example, being included.

PUPIL REFLEX

is of great diagnostic value, and is exhibited in two ways: by narrowing on stimulation by light, and by widening on stimulation, for example, of the skin.

Pupil reflex to light. The patient is placed facing a window, and the hand of the observer is placed over the eye. On the sudden removal of the hand the slightest contraction of the pupil is noticed. The eyes should not be closed by the hand or its removal may be followed by a contraction of the pupil, due to the effort of accommodation which must not be confounded with the contraction due to the stimulation of the light. This accommodative effort of the pupil, which is not a reflex phenomenon, may be separately tested by directing the patient to look first at a distant then at a near object.

Pupil reflex to other stimulation than that of light. In sleep the pupils are very small. Let a person be suddenly awakened by a loud noise or other stimulus, and an extreme dilatation occurs. A similar dilatation may be brought about by a sharp stimulus to the skin. Let the patient look fixedly on a certain spot, say the observer's coat. If now, the skin at the back of the patient's neck be pinched a widening of the pupil ensues. The same reflex may be brought about by a strong faradic current, one electrode being placed at the back and the other at the side of the patient's neck.

PALATE REFLEX.

While the patient is breathing as quietly as possible, with the mouth open, the palate may be touched with the end of a pen-holder. If the part is in the normal condition a retraction follows.

For the sphincter reflexes we must depend in great measure on the history of the patient.

The reflex acts of coughing and sneezing may be tested if desirable, the former by powders blown into the larynx or by observing the patient while choking, the latter by snuff or other irritating substance.

In pathological cases a great variety of new reflexes appear, some following upon external stimuli, others upon natural acts of the patient. As an example of the latter, patients are seen in whom the passage of a stool is followed by clonic contractions in the muscles of the legs.

Among the many illustrations of reflex acts following external stimulus may be mentioned vaginismus, also micturition brought about by the pain of introducing a catheter. In one patient with decubitus washing the sore always induced an act of defecation.

An interesting example of abnormal reflex action was seen in the patient who, though paralyzed from the neck downwards, made a movement with his arm to remove the catheter on every attempt at introduction.

THE RELATION OF THE STATE TO THE INSANE.¹

CHARLES F. FOLSOM, M. D.,

Lecturer on Mental Diseases, Harvard Medical School.

FROM the earliest times, society has recognized its right to protect itself from its dangerous or troublesome neighbors. When offenders were put to the rack, lepers forbidden on pain of death to enter cities, and supposed importers of pestilences were burned alive, or even long after presumed witches ceased to be hanged, the insane, when dealt with at all on the part of the state, if not treated as criminals, were simply put in secure confinement, without reference to their own comfort and happiness, or their estates were placed under guardianship for the benefit of their sovereign or their heirs. Indeed, so late as the beginning of this century medical men in some instances approved or even advised whips, chains, and all sorts of cruel punishment in the treatment of the most refractory of them; the disease had but just been discovered to be to a considerable extent curable; the law held as responsible all that were not furiously mad, or devoid of understanding, like brutes; kindness and humanity in their care and custody were hardly beginning to be observed. Pinel's great reform was only fairly started, Conolly was not born, and with occasional exceptions, asylums for the insane then existing were for the most part mere bedlams, in some of which the miserable inmates were exhibited to the rabble for a few pence each. Their keepers were not seldom convicts, usually brutal fellows, and their custodians far from always had medical training. By the public and their friends, the insane were treated with persistent brutality.

From that day to this, the advance has been simply enormous. Insanity is universally held to be a disease, and as such is studied in medical schools. Insane asylums have largely become hospitals, where pleasant associations and surroundings, the ordinary amenities of life, occupation, recreation, good food, sunlight, and pure air, are to an ever increasing extent taking the place of bolts, bars, cells, gloomy corridors, seclusion, me-

¹ A paper read at the annual meeting of the American Medical Association, in Richmond, May, 1881.

chanical restraint, enforced idleness, and drugs. In the meantime, with a greater prevalence of insanity, which probably is only quite moderate, the increase in the number of the insane known to the community has far outstripped the growth of population; estimates for asylum accommodation, even on a basis considered extravagant, are shown to be below the necessities of the case, as soon as the buildings are completed; new insane asylums are filled almost before they are finished; the most humane and liberal States have not yet been able to provide room for all the insane seeming to require care or custody; each decade the definition of insanity is so widening that persons hardly deemed irresponsible ten years previous are brought to hospitals for detention or treatment, nearly every insane asylum in the land is crowded to overflowing, and still the accumulation of the chronic insane goes on, the proportion of cures of recent cases not increasing in spite of our lavish expenditures.

In Massachusetts, with a census population of 1,783,812 in 1880, there were 4600 insane officially known, 3124 were in public or corporate asylums at the end of the year, or 175.13 to every 100,000 people. This ratio had increased from 9.55 in 1820; 11.34 in 1830; 61.99 in 1840; 84.97 in 1850; 110.55 in 1860; 130.44 in 1870. Two new hospitals just finished in that State are already crowded to accommodate 1200 patients. From all parts of our Union a similar story might be told, except that too often the overfilled asylums would be found wretchedly inadequate to care for a half or a quarter of those fairly needing their shelter. In Massachusetts one in 350 of the population is insane, and there cannot be, I think, less than 100,000 in the whole United States, of whom hardly a third are even receiving asylum care, unsatisfactory as that is in some places, while the utter wretchedness of those in jails, poorhouses, and often private dwellings, is almost beyond belief. Of the total number, probably between ten per cent and twenty per cent. are by our present methods permanently curable, and not far from seventy per cent. should be wards of the state.

At the same time the obscurer forms of mental disease are each year better detected, and under the complex and close relations of our highly civilized life the community demands louder than ever to be protected from Abrahams who murder their daughters in obedience to the voice of a delusion, mothers who drown their children, wives whose hallucinations drive them to splitting their husbands' heads open with an axe, and all persons who under the influence of their insanity expose people to great risks as regards life, comfort, or even decency. The range of insanity is ever widening without any legislation to define it, and it is not at all impossible, that in our own day, even in a government which tries to avoid being too paternal, certain forms of drunkenness, beastly licentiousness, delirium tremens, squandering one's children's all by gambling, etc., may receive the control from the state that the ancient Greeks thought necessary. However, without providing for an increase in the bounds of insanity, we are obliged to associate in our institutions, criminals, epileptics, idiots, demented, dipsomaniacs, those suffering from acute curable disease, the chronic insane, and persons whose insanity is so slightly apparent that most untrained observers would wonder why they were not following their ordinary pursuits in their customary homes, instead of being in confinement.

It is true that the numerous wards of large asylums

admit of a considerable degree of classification, and of a partial separation of the criminals from the law-abiding, the violent from the calm, the destructive from the quiet, the dangerous from the peaceful, the obscene and profane from the well-behaved, the sick and bedworn from the noisy and active, the dement or idiot from those of clear mind, the prostitute and the infanticide from the plodding day laborer and the woman of refinement whose poverty compels her when insane to become an inmate of the public asylum. There is still, however, such a similarity in the various rooms and galleries and corridors, and such a close relation between them, that there is great danger that those least ill, or in the curable stage, will be subjected to restraint not needed by them, or indeed to an amount of restriction of liberty that is not justifiable and to associations that must be at least very painful, if not absolutely injurious or fatal to recovery. Indeed, the case can hardly be otherwise, when we bear in mind the facts that the hospital for the insane of to-day is simply an outgrowth of the prison asylum for lunatics of a half century ago, without sufficient structural change to correspond with its present function, and that in each the number of physicians and attendants, too many of whom are inadequately trained for their work, is so small, that convenience of administration is an absolute necessity in its construction, to the exclusion, in a considerable degree, of considerations for the welfare of the patients and strictly medical treatment.

The problem of properly caring for so many persons in such a variety of mental and physical conditions is so intricate and difficult, that it cannot be said to be satisfactorily solved anywhere. The colony at Gheel with its pauper lunatics hired out to peasants furnishes some suggestions to us, but little real help, its chief lesson being that some of those previously deemed incurable and useless may by employment regain their apparently lost faculties and return to the duties of a restricted life; the 10,000 unhappy insane huddled together in the five enormous asylums of London warn us what to avoid; the 1500 boarded out in private families in Scotland, under the supervision of the Lunacy Commission, only make us to that extent envious of social conditions where it is possible to get so good care, and so cheap, in that way. With very few private and corporate asylums, and these chiefly for the wealthy, we must provide for a very heterogeneous mass of humanity, accustomed to very different associations and methods of life.

For those of the insane who are deprived of their liberty, as occupants of private dwellings, workhouses, almshouses, or insane asylums, society in protecting itself should at least do the justice of seeing that they have all the freedom and comfort which is compatible with safety, and not prejudicial to the recovery of those who are curable. All experience has shown that the interests of the insane are best served, and that they are surest to receive the most intelligent and humane care, where there is supervision on the part of the state, by a competent expert board, appointed solely on account of its fitness for that duty. The best form yet attained for the purpose is, beyond all question, the Scotch Lunacy Commission, whose operations will well repay a careful study, although the French and English methods have many advantages.

In our country a national lunacy commission, with the power given to similar boards in Great Britain, would be out of the question, for obvious reasons, al-

though I feel confident that the appointment of a United States Commissioner of Insanity, with chiefly advisory duties, like the Commissioner of Agriculture, is only a matter of time. A state board or commissioner is so likely to be under the influence of local politics, that one deserving the confidence of the community could be secured, if at all, only by a strong effort and constant watchfulness on the part of influential and disinterested men; but the great good that has resulted from such organized central inspection in other countries, and the need of similar state control is so clear in the United States, that it is to be hoped that we shall not be slow in treating with simple justice a large class of persons, whose infirmities expose them to so much bitter suffering that is unavoidable. It should be distinctly said, however, that a central board organized on a political basis is hardly better than none at all, and that if the commission is not of the best men, it is likely to do at least as much harm as good, or to be worse than none, especially in those states where the asylum governing trustees are men of high character, appointed by the chief executive from various sections, and not as in England and Scotland with purely local interests.

First of all a lunacy board must embrace men with a thorough medical knowledge of insanity and its treatment, and be capable of advice or action that will command respect with the community, the medical profession, and the asylum officers. Its chief duties would be:—

I. To secure proper care for the insane in private dwellings; they are very much more liable to neglect and abuse than if in well regulated public institutions. This, too, should include the right to send to asylums all that might not be receiving suitable care outside, but as insanity is not a crime it is desirable that as many of the insane as is practicable should have natural home life, at least that their liberty should be interfered with to the least possible extent for their own protection and cure, or for the safety and welfare of the community. Allied to this part of the central board's duty would be its obligation to encourage the construction of suitable asylums in the many States where they are urgently needed, and to remove the insane from any jails and almshouses where they cannot be treated in conformity to the requirements of their case.

II. The board should supervise the commitment of patients to asylums by receiving copies of the commitment papers, and also, within a month of the patient's arrival there, a certificate from the medical superintendent (1) as to their insanity, and (2) as to the propriety of their detention for care or medical treatment. This would secure greater care than is now customary, and would involve a thorough examination of all cases, especially if defective or faulty certificates were returned for correction, in default of which the persons committed might or might not be discharged, according to the circumstances of each case. I fear that this matter does not receive from the medical profession that consideration which its importance deserves. If we send a patient to Florida for the winter or to Europe for the summer, thereby involving a comparatively trifling interruption to his business, it is usually only after weeks or even months of deliberation and perhaps painstaking consultations, but if to an insane asylum, with its attendant possibilities of injuring for many years or for life, cherished plans for the future, it is too often upon a hastily formed judgment or the

statements of friends, perhaps interested, whether consciously or not.

As insanity is a disease, it is well that it should be upon the shoulders of properly qualified physicians that the tremendous responsibility should rest of saying whether or not a person is a fit subject for an insane asylum, and as that necessitates serious loss of personal liberty, it is equally clear that the actual commitment, after proper application from the nearest friend or local magistrate, should be a judicial—at least a ministerial—act by a legal officer, who, at his discretion, may dispense with the appearance before him of any insane person who may be likely to be harmed by being subjected to public examination, if there be satisfactory evidence that it is not needed.

The definition of insanity really depending upon the opinions of the signers of the medical certificates, supported by public opinion and the decisions of the courts, the patient committed should always clearly understand that he has the right of appeal for an examination of his case, immediately after his commitment, or at any time, to an impartial expert board, who should have the right of discharge whenever it were deemed best, whether the insanity be clear or not, except in criminal cases, if the detention in an asylum should be decided to be uncalled for. Nothing short of this can fairly satisfy the right of the insane to be sure that there is no error of diagnosis or judgment in their case, and that, if they are improperly confined or not insane, a fair investigation will soon set their affairs right. It has been suggested in England that a few paid experts be assigned to the duty of seeing all persons where commitment to insane asylums is demanded, but I am quite sure that, outside of the practical difficulty of having to await their convenience in getting from one part of the state to another to sign certificates of insanity, it would be unwise to limit the power of certifying to so small a number of persons.

The certificates of insanity signed by two physicians independently of one another, and certainly within a week of their examination, should bear the dates of signature and of seeing the insane person; they should include the facts indicating insanity as observed by themselves and as communicated by others. One of the medical men certifying should be unconnected with any hospital for the insane, and neither ought to be an officer in the asylum to which the commitment is made. All patients, private or otherwise, including the pauper insane sent to those exceptional almshouses or workhouses that are fit for them, should be subject to the same regulations as to commitment. It would be a better method if workhouses and almshouses receiving the insane should be required to have special wards for their use, and to admit them only after they had been, upon sufficient examination and observation, transferred by the central board from a regular hospital for the insane.

An insane person arrested away from his dwelling, or without a definite home, or so violent or dangerous as to need immediate custody, or simply requiring undelayed care, when the committing judge is not at hand, would be subjected to the needless cruelty of confinement in a "lock-up" if no special provision were made for such an exigency. Probably no better way out of the difficulty can be devised than to allow commitment upon an emergency certificate, signed by the applicant, whether relative, friend, magistrate, or

policeman, and accompanied by at least one medical certificate, proper security, a bond if need be, being given that the process of committal as required by law shall be completed within three days, in default of which the patient should be discharged, the lunacy commission being informed of all the facts of the case in any event. Naturally no officer in the asylum to which the emergency patient is sent ought to be allowed to sign the emergency certificate.

The courts, of course, should have the power to commit any insane person to an asylum upon complaint, and after inquiry, or even in case of crime before indictment, upon failure to indict, during confinement awaiting trial, or after sentence; and all persons acquitted of crime, by reason of insanity, should thereafter undergo confinement in an insane asylum. The discharge in these cases should always be a judicial act, the medical officers informing the committing authorities of restoration to sanity. In case of remote districts, away from medical men or from a judge having power to commit, and in order to provide for the insane needing immediate care, it is quite important for the local authorities to have power to bring persons of unsound mind before the proper officer, who should also be able to summon them at his pleasure. It is proper, too, that in some cases at the discretion of the asylum authorities, where a certificate of insanity is not desirable or not legal, individuals should be allowed upon their written application to become voluntary patients, to be permitted to go away within three days after signifying their desire to do so, the three days' provision being made with their consent upon entrance, and being intended to prevent a person, quiet at first but afterwards become violent or dangerous, from suddenly bursting out upon the community without warning to those whose duty it would be to secure at once a proper commitment.

The question would naturally arise what security have the insane against too long detention, the medical men who see them every day not having their attention directly drawn to that point as often as might be desirable. The difficulty may be partially met by having every commitment paper valid only for a definite period of one, two, or three years, at the end of which time the medical superintendent should be required to examine his patient carefully, and certify anew to the central board as to his insanity, and as to the propriety of further detention. The board, as expert, too, should be constantly making investigations with regard to that point, and the rule should be followed of allowing the safe patients to try outside life too often rather than not often enough.

The lunacy commission or commissioner, having the right to discharge any insane person upon inquiry, should also be empowered to transfer paupers from one institution to another without obtaining fresh commitment papers.

III. While in the asylum or elsewhere the insane should always have the right to consult the central board, and to that end must be allowed to send to the board, and to receive from it unopened letters by mail, without the delay caused by the periodical emptying of locked letter boxes. Letters sent to others than state officers should be indorsed and kept for the relatives or inspectors, as in England, or disposed of as the judgment of the superintendent dictates, according to Scotch law; the nearest relative, and as many others as is proper in each case, of course having the right of

unrestricted correspondence. The admission of friends must necessarily be under the control of the medical staff of the hospital, a list being kept of those refused entrance, and there resting with the central board power to authorize any person for sufficient reason to have permission to visit any inmate upon its written order.

IV. Especially, as it is well to encourage the greater use of private asylums in this country, the board should be required to see that means are taken to sufficiently guard the property of all the insane under confinement, and whenever one of them is not receiving the benefit of a fair proportion of his estate to report the facts in the case to the attorney-general, whose duty it might be to direct inquiry for the purpose of securing justice in the matter. As a rule, such a regulation would probably result in an agreement being made between the parties interested, with the consent of the board. Too many of the insane live without the comforts to which they have been accustomed, the property rolling up for their heirs, when the legitimate use of their income might make them incomparably less wretched.

V. The board should have authority to visit at their pleasure, and fully inspect all places in which an insane person is confined, seeing personally each patient at definite intervals of time, and with proper safeguards examine all places where one is alleged to be under detention, the overseers of the poor being required to report to it all persons in their town or city known by them to be of unsound mind. It should have such direction and regulation of all matters relating to lunacy as each State might think best to give it, a great deal being left to harmonious coöperation with it on the part of the asylums rather than to legal enactment, for it is much easier and more disastrous in its possible results, to place too much power than too little in supervisory hands. The board should be enabled to ask for any facts, to make inquiries, summon witnesses, examine on oath, require records of mechanical restraint, seclusion, and general matters of management, give and renew licenses for private asylums, receive notice of all deaths, accidents, escapes, or maltreatment by attendants, and make an annual report of all its doings. It should see that penalties are enforced for non-compliance with the laws for the protection of the insane, for neglect of duty, or abuse of patients, and should keep a list of all discharged officers to be furnished to the several institutions. The laws regarding settlement of paupers, so far as the insane are concerned, should be enforced by the board, and all questions regarding them should be decided by it under the statutes.

VI. Perhaps not the least valuable work to be done by a lunacy commission would be the proper classification of the insane, and more promising treatment, by establishing a separate asylum for criminal lunatics, another for idiots, still another for paralytics, insane epileptics, and demented, and a self-supporting institution for dipsomania and allied forms of drunkenness by removing suitable persons to those few almshouses and private dwellings which are adapted to their proper care, and, most important of all, by insisting upon well appointed hospitals, in the strict sense of the word, with all the best resources of our skill and the most approved appliances of art for treating curable mental disease. By tact and wisdom an incalculable amount of good might be done in this direction, which would finally reach out so as to embrace every ques-

tion involving the welfare of the insane and the duty of society to that unfortunate class.

Finally, every officer of the central lunacy commission should be required, as in Scotland, to take an oath to keep secret all such matters as might come to his knowledge in execution of his office, except when required to divulge the same by legal authority, or as far as he should feel called upon to do so for the better performance of his duty.

In the necessarily brief time which I have felt justified in occupying, I have endeavored to give an outline, in as concise a manner as possible, of what I conceive the simple duty of the State to the insane to be, in a most important matter, touching the direct interests of most—at least the sympathies—of all of us here. Where so much demands accomplishment, cannot our noble profession inaugurate measures to bring about the changes that are required, and help to guide a movement, which, with fewer or more mistakes as we "coöperate" or not, an enlightened public opinion must sooner or later set in motion? The superintendents of our asylums are doing a vast deal in the direction of improved methods for the treatment of the insane, for which they deserve the gratitude of the profession and of the public. They will be only too glad to coöperate in any wise way for carrying that work still further.

LITHOTRIPSY, WITH ENTIRE REMOVAL OF FRAGMENTS AT SAME SITTING BY BIGELOW'S ASPIRATOR.¹

BY NORMAN L. SNOW, M. D., OF ALBANY, N. Y.

SURGERY is constantly making rapid strides, not only in the matter of wholly new and original operations, together with many useful and happy modifications of almost classic methods, but as well also in the mechanical department. In fact, this latter must keep pace with the former, and the majority of surgeons owe to some brother operator, or mayhap ingenious inventor, much of the credit that accrues to them through brilliant results by the more ready methods. Now if this be so in a general sense it is especially true of certain departments, and in no one perhaps in a more marked degree than the genito-urinary. Of the divisions of this latter, perhaps, the bladder can justly claim an equal share, and for the present demands our attention in the consideration of stone and its removal safely by the most speedy method.

Lithotomy is probably the oldest, and litholapaxy, so called, the most recent, lithotrixy and lithotripsy occupying a more intermediate position as to advocacy. Mention of boring and crushing stone in the bladder is made in the Hippocratic writings, but seems not to have been practically carried out, and it was not until as late a day as 1813 that the operation seems really to have been undertaken with any degree of success. In 1817 Civiale's attempts first became noticed, and after more fully perfecting both method and instruments he satisfactorily demonstrated his ideas on the living subject in 1821, and thus established for the operation a permanent place in surgery. His method, however, was lithotrixy proper, the stone being drilled and crushed or ground, the detritus being partly washed

out and partly expelled by the bladder. The operation of lithotripsy, or crushing, had not up to this time been undertaken, the first instruments for which were not constructed until some months after Civiale's public demonstration. Mr. Hodgson, of Birmingham Hospital, was the first to give prominence to this latter method by a successful operation in 1825. Since this date both operations have steadily progressed in favor and nicety of accomplishment under the leadership of such master spirits as Civiale, Baron Heurteloup, Brodie, Aston, Key, Ferguson, Hawkins, Coulson, and Sir Henry Thompson, until it seemed very little more could be desired. But the end was not yet, for with all their skill and ingenuity, and notwithstanding the evacuating apparatus of Sir Philip Crampton and Mr. Clover, with Thompson's modification of the latter, more than one sitting was usually found necessary to fully complete the operation, and it fell to the lot of our distinguished countryman, Professor Bigelow, to so perfect the mechanical part as to render unnecessary but one attempt at the complete removal of any stone capable of expulsion in this way. This was brought about more by fearlessness on the part of the operator than by any marked improvement in appliance, as in his procedure time is a factor of no importance, a directly opposite conclusion from that of all prominent authorities, and the key-note to all future successes in this direction.

Formerly, when lithotomy was much practiced, the small and brittle stone was operated on with more anxiety than the hard and larger; now, on its first detection the surgeon feels he can relieve the bladder of its enemy without endangering his patient but little more than if he were simply to introduce a large bougie.

CASE. Robert A., American by birth, age fifty-three, average weight one hundred and sixty-five pounds, height five and a half feet, habits regular, temperament sanguine nervous. No family history of any moment; neither rheumatism or gout had been inherited; father died at age of fifty-six from lung trouble, resulting from exposure. His early life and manhood had been passed in the West, where the water-supply was from the turbid Mississippi and vicinity. A cigar maker by trade, he worked for a number of years at "damming tobacco." In this the operator is obliged to stand at a bench, moistening the tobacco with a spray of water ejected from the mouth. In this way swallowed a quantity of water, in addition to which he drank a great deal of same fluid. Of English descent, he inherited a fondness for hearty living, and was in the habit of indulging in hot meat suppers, drinking at times a moderate quantity of ale or lager. Did not take much out-door exercise, and was not very cautious of exposure. Often when fatigued would take large draughts of ice-water and sit in currents of air. Was always well, so paid little regard to preservation of his health. Contracted gonorrhoea when a young man, and this became a long-continued gleet. Has had several slight attacks of rheumatism, but general health good. First noticed trouble in micturition in spring of 1879, symptoms being pains in back, loins, and thighs, with frequent desire. For this I was consulted in June, 1879, his weight at that time being one hundred and sixty-seven pounds. So frequent was the desire to urinate that he had constructed at his place of business a urinal handy by his work, and thus saved a great amount of running up and down stairs.

At no time had there been any evidence of renal cal-

¹ Read at a meeting of the New York State Medical Society, February, 1881.

culus or kidney disturbance. During the summer of same year received a severe fall striking lumbar region on back of a chair; the pain was very severe but yielded to simple treatment. Consulted me in November, 1879, for a feeling of weariness about back, loins, and thighs, accompanied by frequent urination with pain and tenesmus, also burning in perineum and end of penis. Urine contained pus, mucus, oxalate of lime, uric acid, and bladder epithelium. Put him on the alkali anodyne treatment with strict injunction as to hygienic details, dieting, etc. Diagnosed chronic cystitis and symptoms continued during following winter with remission and exacerbation.

Examined for calculi at different times but could detect none. The bladder was washed out several times during the winter and spring, with different medical solutions, the walls each time being well distended.

An analysis of urine in June, 1880, gave 1022, neutral, trace of albumen, blood, mucus abundant, uric acid crystals and epithelium. Was advised a change during heated term and accordingly went to the Canadas. Was greatly benefited thereby and remained very well until the cooler months, when a relapse of the old trouble came on. Could now retain his water but a very short time, and had a pain along urethra, stream often double, stopping at times then recommencing. Voided it best in recumbent position. Pain in glans penis was described like tingling of a nerve in end of finger. Examined him in October with Thompson's short curved sound and detected a roughened gritty feel in left posterior fundus of bladder.

One month later, at my suggestion, he was seen and examined by Dr. Van Derveer, who felt quite positive he detected a small stone. In December it could be distinctly felt, and for a few weeks seemed to increase rapidly in size so that a very satisfactory click could be obtained. Advised an operation, to which he readily assented; accordingly on December 27th, assisted by Drs. Van Derveer, Shanks, Perry, and Mr. Furbeck, student, the operation of lithotripsy was undertaken. The bowels had been moved the night before and a light breakfast had been taken; ether was administered by Dr. Perry, the patient coming under its influence nicely.

The bladder was injected, and a lithotrite having been introduced, the blade was pressed well back against the posterior fundus, the stone being seized quite readily. It proved quite brittle, all portions being crushed in a short time. Experienced but little difficulty in the introduction of Bigelow's large sized evacuating tube, and a moderate suction force with the exhausting bulb soon gave evidence in the glass receiver that the work had been satisfactorily accomplished. Was obliged to re crush a fragment too large for the tube, but this was soon disposed of. An introduction of sound failing to detect the slightest remaining portion the operation was completed.

Entire time occupied was thirty minutes, weight of fragments eighty grains. No vomiting or unpleasant effects from ether, an unusual circumstance. The patient was placed in bed between woolen covers and given ten grains of sulphate of quinine with slight anodyne. Found him on evening of same day quite comfortable, had no chill, passed water quite freely, there being but a slight tinge of blood. Some pain in iliac region, but on the whole comfortable.

December 28th. Passed a good night, perspiration free, some uneasiness and smarting in passing water,

but no severe pain. Blood continues to be present in small quantity, temperature and pulse good.

On the second day introduced a soft catheter easily, and washed out the bladder. Continued quinine in two-grain doses four times daily, with instructions to use diluents freely and exercise care in diet.

By the fifth day temperature and pulse were normal, bowels open, and water passing nicely, patient able to be up and about the house, and on January 6th, ten days from date of operation, although the weather was extremely cold, he was able to attend to business.

THE TREATMENT OF SINUSES BY TENTS.

BY EDWARD T. WILLIAMS, M. D.

THE knife, in modern surgery, seems to be regarded as the panacea for every ill. It was otherwise among the ancients, who, though behind us in knowledge, often showed themselves before us in common sense. They always viewed the cutting instrument in its true light, as the surgeon's last and worst resort. The popular method of treating sinuses is a good illustration of this backward progress of surgery. We hardly hear nowadays of any way of treating a sinus except by laying it open. This leads me to speak of a simpler method which I have tried successfully a number of times,—the use of tents. I speak only of simple sinuses, such as are usually treated by cutting. Take a narrow strip of sticking plaster and fold it or roll it lengthwise between the fingers, as one rolls a slip of paper to light a lamp or cigar. Push it to the bottom of the sinus, and leave it three or four days, till it excites a healthy suppuration. Then remove the tent, bring the walls of the sinus together if necessary by a bandage or adhesive strips, and let it heal from the bottom like a fresh wound. This acts on exactly the same principle as the knife or caustic, namely, by exciting an active and reparative inflammation in the place of a chronic and stationary one. I do not say that it will take the place of the knife in all cases, but it certainly will in many. It is an old plan, but one that ought not to be dropped altogether out of mind. It is beyond doubt that *fistule in ano* have often been cured by this method, or by the seton, which acts in the same way, and that this is the real secret of the success obtained by certain empirics in the treatment of that disease.

Two special applications which I have made of the same essential principle I would like particularly to notice.

The first is the application of a *bougie à demeure* as a substitute for cauterizing or curetting the uterus in chronic endometritis. Pass in a common urethral bougie and let it remain a short time in the womb. I have never ventured to exceed five or ten minutes, but have seen it followed by a decided relief of symptoms.

The second is the same thing applied to the urethra (male) in cases of gleet and seminal emissions. Both these conditions, as it seems to me, are most frequently kept up by a kind of chronic prostatic urethritis, with probably a granular condition of the mucous membrane. The prostatic portion is supersensitive, and sometimes bleeds a little on the passage of an instrument. The *sonde à demeure* is admirably adapted for these cases, and though perhaps less effective in a bad

case than cauterization, has neither the risk nor the painfulness of that method. The principle, in all cases, is exactly the same, the substitution of an acute inflammation, with a tendency to heal, for a chronic one with a tendency to persist.

RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

TOXICOLOGY.

Ptomaines. T. Husemann¹ gives a summary of the observations already published on this class of bodies, and considers the very important bearing they have on the study of poisons and on forensic medicine. These substances resemble the vegetable alkaloids closely in their chemical reactions and physiological effects, and it is important to discover, if possible, reactions which will distinguish between these poisonous bodies, which are the result of putrefactive processes, and those similar vegetable principles which, when administered, may produce death. "Ptomaines" seem to have different physiological actions. Some appear to act as poisons, others are inactive; whilst others counteract the effects of poisonous substances.

The study of these bodies embraces also the poisonous effects produced by food in certain conditions of putrefaction or fermentation. Panum showed that albuminous substances by putrefaction yielded a poisonous body, acting like a ferment, soluble in water, insoluble in alcohol, and capable of withstanding a temperature of 100° F. This has been confirmed by Bergmann, who describes a compound called *sepsin*, generated by putrefaction. It appears from the researches of Panum and Schwenger that compounds having different physiological actions are produced at different stages of decay.

Sonnenschein and Fuzler found in an anatomical maceration fluid an alkaloid which resembled atropia in its action, and poisonous sausages produced a similar effect; the existence of a product of decay which caused tetanic symptoms was also noticed. Aebi and Schwazzenbach detected a compound allied to an ethereal salt in the extract from dead bodies. Substances derived from putrefaction of maize certainly produce tetanic symptoms, as was first proved by Lombroso and Erba, and this action has been traced to the presence of basic substances. Frequently the tetanizing principle in the maize extract has its action masked by a narcotic substance; just as Ranke showed that the physiological action of strychnia in bodies long buried may be masked by ptomaines.

The relation of these products of putrefaction to certain diseases is evident from the fact that Sonnenschein's alkaloid is found in the bodies of patients dying from typhus fever, and many individuals poisoned by decomposing food show marked typhus symptoms.

In many cases of poisoning by cheese it was found that the bad effect was not due to vegetable growths or to microscopic organisms, and the cheese was frequently fresh.

It appears from the study of the literature concerning ptomaines that they are usually produced in bodies which, after brief exposure, have been excluded from air, as in buried bodies, sausages, and tinned foods;

and further, in these cases, the production chiefly occurs in the internal portions. Cases, however, are known where similar principles have been present in comparatively fresh substances which have been constantly exposed to the air; hence under the name "ptomaines" must be included all alkaloidal products of decay, whether formed in the presence or absence of air.

P. Spica² obtained, by Dragendorff's process, four of these bases from the liquid taken *during life* from a case of peritonitis, which had taken on a suppurative form. Their chemical reactions and physiological effects are described in the original communication. All were poisons; three, however, only in a trifling degree. The fourth was poisonous in minute doses, and resembled curare in its physiological effects.

Jansen³ has described at length the chemical and physical properties of ptomaines. The original article, which is of interest to toxicologists especially, must be consulted by those who desire information concerning this part of the subject. According to Jansen, the symptoms produced by poisonous ptomaines are the following: immediate contraction, rapidly followed by dilatation of the pupil, immediate diminution and irregularity of the heart-beat, convulsive movements.

Brouardel and Bontmy⁴ have detected several of these ptomaines; in one case in the organs of a person who had died from the effects of carbonic oxide; in a second case in the organs of a person who had died from the effects of white arsenic. This latter alkaloid had been previously detected twice by Selmi under similar conditions. According to the authors, each case of putrefaction does not give rise to a distinct ptomaine. For example, they found the same ptomaine in the organs of two persons, one of whom died from carbonic oxide, the other from prussic-acid poisoning. Brouardel and Bontmy met with an alkaloid resembling veratria in a body which had lain eighteen months in the Seine, and another in a goose which had been subjected to the heat necessary to cook it. They consider many of these ptomaines poisonous to man, and ascribe to them the poisonous effects which are sometimes produced by food of various kinds. They mention a case in which twelve persons were attacked with all the symptoms of acute poisoning after eating a tainted goose, which was found upon analysis to contain a liquid ptomaine analogous to codeia; of these twelve persons one died after some hours. The symptoms were nausea and repeated vomiting.

Ptomaines presenting in general the more important chemical and physical properties of the vegetable alkaloids may readily be confounded with the latter. The proper method of distinguishing the two consists in determining *all* the chemical and physical properties of the toxic base isolated and comparing them with those of the vegetable alkaloid whose presence is suggested. This method can, however, be employed only in cases where the quantity of the poison isolated is tolerably large. Brouardel and Bontmy⁵ have endeavored to find a reagent which is sufficient in all cases to disclose the character of the alkaloid extracted, and think they have discovered such a reagent in potassium ferri-cyanide. If the latter is instantly

changed to potassium ferrocyanide (determined by neutral ferric chloride), and at the same time the base is precipitated by iodo-mercurate of potassium, the base in question is a ptomaine; if the ferrocyanide is unchanged and the substance behaves with the iodo-mercurate of potassium as do the vegetable alkaloids, the base is a vegetable alkaloid. In applying the test the base is converted to a sulphate, and a few drops of the solution of this salt are placed in a watch-glass containing a little ferrocyanide in solution; a drop of neutral ferric chloride is then added. According to the authors, morphia and veratria, of the vegetable alkaloids, are the only exception to the above.

Ch. Tanret¹ has repeated the experiments of Brouardel and Boutmy, and although he finds that ptomaines produce the change above described, they do so only slowly. He also finds that a similar slow change is produced by crystalline ergotinine and aconitine, and by amorphous and crystalline digitaline; while the change is produced instantaneously by morphia, eserine, liquid hyo-cyania, and amorphous aconitine and ergotinine. Great caution should therefore be taken in employing the test, the more so as the list of vegetable alkaloids is probably far from complete.

Arsenic. A case of poisoning having occurred in which food containing arsenious sulphide was suspected, Ossikovsky² was led to make experiments to determine whether it is possible that, during the process of putrefaction of organic bodies, arsenious sulphide may be converted into oxide. It is generally supposed that *pure* arsenious sulphide, however prepared, has no poisonous action on the living organism. The author therefore considers that in the case in question the arsenious oxide must have been present as an original impurity (as is sometimes the case), or as a product by chemical change of the sulphide.

Experiments were made by exposing a mixture of arsenious sulphide, water, and pieces of decomposing pancreas to a temperature of 35 to 40° F. for a period of seven days. Samples for analysis were removed at intervals and filtered; the filtrate, on being acidified, yielded a precipitate of arsenious sulphide, and the acid filtrate was tested for arsenious and arsenic acids. It was found that precipitated arsenious sulphide was much more rapidly oxidized under these circumstances than the more compact crystalline orpiment, but the result obtained from both kinds of sulphide was similar. The albuminoid bodies present, on decomposition, yielded ammonia, which dissolved a portion of the sulphide as such; this was precipitated on acidifying the liquid with hydrochloric acid; the arsenious sulphide was also oxidized to arsenious acid and to a smaller extent to arsenic acid; the quantities of these oxidation products formed increasing in proportion to the time.

Further experiments proved that in the absence of the pancreas the presence of water at a moderate heat was sufficient to convert the precipitated arsenious sulphide into arsenious but not into arsenic acid. The author further tried the effect of making the liquid in which the arsenious sulphide and decomposing organic matter were present alkaline with sodium carbonate, so as to imitate the conditions existing in the large intestine where alkaline secretions would mingle with the food. It was found that the quantity of oxidized

arsenic compounds formed was quite sufficient to produce poisoning.

F. Selmi³ is undertaking experiments to ascertain in what state arsenic occurs in the urine of subjects poisoned with this substance. Arsenic was administered to a large dog in doses too small to produce fatal effects, and the urine examined over a considerable period. It was found that during the first period of three days the urine contained an acid of arsenic, precipitable by baryta, and another arsenical compound which was not precipitated by baryta; the same substances were found in the second period of five days, besides a volatile arsenical compound which gave a crystalline hydrochloride; subsequent to this the arsenical base gradually disappeared.

According to E. Reichardt⁴ it is unnecessary, in testing the urine for arsenic in cases of chronic arsenical poisoning, to destroy the organic matter. The urine (one or two liters), acidified and gently heated, may without further treatment be saturated with hydrogen sulphide. It is then allowed to stand, covered, for twenty-four hours, after which it is filtered, and the precipitate examined for arsenic by appropriate methods. The same is true in case lead, bismuth, copper, antimony, or mercury are to be sought for.

Ch. Brame⁵ employs baryta instead of potassium cyanide or black flux for the reduction of arsenious acid. The reaction manifested by the mixture of arsenious acid and baryta heated to redness is instantaneous, and is not accompanied by any disengagement of moisture. The ring formed has a perfect metallic appearance. There is formed, besides metallic arsenic, barium arseniate, which may be dissolved in nitric acid and tested with silver nitrate. Analogous but less marked results are obtained with lime, potassa, and soda. Arsenic sulphides also yield metallic arsenic with baryta, though less easily than arsenious acid does. In the case of orpiment there is deslagation.

Investigations on the localization of arsenic in cases of poisoning have been previously noticed.⁶ E. Ludwig⁷ has further studied this question, and gives the following *résumé* of the results obtained by him from experiments made upon animals as well as from cases of poisoning in man:—

In cases of acute as well as chronic arsenical poisoning arsenic is taken up by the bones in small yet distinctly recognizable quantities. If the case is non-fatal arsenic may be found in the bones a long time after the last administration. In one case arsenic was found in the bones on the twenty-seventh day after the last dose; in one case, examined forty days after the last administration of the poison, the bones contained none. It is worthy of note that the liver in both these cases still contained arsenic.

In the brain, in cases of poisoning, both acute and chronic, only a small amount of arsenic is to be found, while the liver and kidneys contain a comparatively large quantity.

The kidneys in acute cases may contain a larger proportion of arsenic than the liver. The muscular tissue contains only a small quantity, but always more than the brain.

Arsenic is found in the liver for a longer period than

³ Journal of the Chemical Society, London, May, 1881, page 311, from Gazz. Chim., x. 431.

² Journal of the Chemical Society, London, March, 1881, page 123, from J. pr. Chem.

in any other organ. Ludwig's paper is a long one, and contains in full the results of his investigations.

Ludwig's conclusions are confirmed, in a case of poisoning from Paris green, reported by Bergeron, Delens, and L'Hôte,¹ who found seven times as much arsenic in the liver as in the brain. The kidneys and muscular tissue also contained more than the brain.

S. W. Johnson and R. H. Chittenden,² in a case of arsenical poisoning reported by them, also found the amount of arsenic in the brain to be less than in any other organ.

In another case reported by Johnson, — a case of acute poisoning, — 83.23 grains of arsenious oxide were found in the stomach, liver, and other internal organs, while the brain contained a hardly perceptible trace of arsenic.

Johnson and Chittenden also report the results of an experiment conducted on a large dog, to which was given 6.5 grammes solid arsenious oxide, mixed with meat, during a period of eight days, in doses increasing from 0.1 gramme to 2.5 grammes per day. The dog was killed twenty-four hours after the last dose. The intestines, liver, kidneys, muscular tissue, urine, brain, and blood were examined. Of all these the brain contained the least arsenic.

It appears, therefore, from the cases which have been reported, that the amount of arsenic absorbed by the brain is very small compared with the amount absorbed by the other organs and tissues.

R. H. Chittenden and H. H. Donaldson³ have contributed an article On the Detection and Determination of Arsenic in Organic Matters, which is of interest to toxicologists, but unsuitable for a detailed notice here. The process which they recommend for the destruction of organic matter is Gantier's,⁴ somewhat modified; and for the quantitative testing of arsenic they recommend the decomposition of arseniuretted hydrogen by heat. They describe a form of Marsh's apparatus so modified as to furnish a slow and even evolution of gas, so that all loss may be avoided; and to still further prevent loss they employ the process recently described by Gantier,⁵ in which he controls the evolution of gas by slowly introducing the arsenic mixed with a definite quantity of dilute sulphuric acid of known strength, later adding the same quantity of a stronger acid, and lastly a still stronger acid; the increasing strength of acid added counteracting the diluting effect of the reaction, so that the strength of the acid remains about the same during the entire process of two and one half to three hours. The strength of the acids employed is given. They decompose the gas by passing it through a tube heated for a distance of six inches. Under these circumstances no trace of arsenic passes by. The arsenic is weighed as metallic arsenic. The whole method is recommended as being accurate, delicate, and requiring the use of but three chemicals, — sulphuric acid, nitric acid, and zinc.

The authors state that, contrary to the prevailing opinion, the presence of organic matter, even in considerable quantity, does not interfere with the detection and determination of arsenic by Marsh's test. Frothing, due to organic matter, may be prevented by

introducing fifteen drops of sweet oil, which floats on top. The only other things to be guarded against are, first, the too rapid introduction of the acids, whereby loss as well as frothing of the mixture may ensue; and secondly, the heating of the flask by the chemical reaction. The latter may be prevented by keeping the flask surrounded by cold water. The paper contains the results of numerous experiments.

(To be concluded.)

Hospital Practice and Clinical Memoranda.

THREE CASES OF UNILATERAL CEREBRAL HYPERÆMIA.

BY GEORGE JEWETT, M. D., FITCHBURG.

CASE I. The subject of this history is a stout, robust woman of thirty-six years, and at the time of the attack of which I am about to speak was the mother of four children. She has borne one since. All are remarkably well and strong.

December 18, 1875, Mrs. D. was busily sewing near a furnace register, and did not notice the continued increase of heat until she observed herself in a profuse perspiration. She was dizzy, her head was hot, and felt badly. These sensations but partially left her during the following night and day. The second night, while in the act of lying down, she suddenly became violently dizzy and unconscious. Consciousness returning, she began to vomit. Passing an unknown time in vertigo and nausea, she finally observed that when lying on the right side all her distress quickly left her, and she soon felt in her usual health. It, however, instantly returned when she rotated her head to the left of the median line or lay flat upon her back. She could nurse her babe, then about a month old, only when lying well on her right side, and partly on her face and chest. She slept but little during the night, and I was called the next morning. She was sitting up; her face was flushed, apparently from mental anxiety, and she was a good deal frightened on account of the anomalous symptoms from which she suffered. The pulse was a little quickened, temperature and respiration normal; she had some appetite, and the bowels were regular. There was no disturbance of tactile sense nor paresis. She stated she was comfortable every way provided she kept her head well to the right and forward of the vertical line, and was able to attend to her ordinary family duties provided they did not interfere with the prescribed position of her head. She could not, however, lie flat upon her back without an instant return of the vertigo and nausea. She continued in this condition, with only a slight amelioration of symptoms, for about two months. When in the act of sportively tossing her baby, she lost consciousness, dropped her child, and fell. There was no epileptic cry or convulsions, and return of consciousness was immediate and complete. She now observed she could not drain a drinking cup, as the tipping the head backward immediately brought a return of the dreaded vertigo and nausea. Sometimes on rising from a stooping position she would stagger backward, unable to recover herself until arrested by the wall of her room.

On lying down, she often experienced a sensation in

¹ *Annales d'Hygiène*.

⁴ *Vol. of this Journal*, January 14, 1876, page 49.

⁵ *Bull. de la Soc. Chim.*, xxiv, p. 258.

the vertex, as if the blood rushed with a crash or splash. About three months from this date, she discovered by experiment that she could turn to the left in bed, provided the whole body was turned at the same time. A year elapsed before she could tip her head backward to rest it upon the back of a high chair, unless it was well rotated to the right. Previous to the attack her eyesight was unusually strong, but a year afterwards she was obliged to wear glasses about her ordinary work. She could not read on account of a "small black spot" always present, which seemed to follow the outline of the letters, so she could not make them out. In sewing, the ever present "little black spot" always came to play its mischievous pranks and annoyed her much. If she attempted to sew on black cloth, her sight was impaired for several days afterwards. The defect in sight, she thought, was mainly in the left eye. The flitting black spot seemed in the left eye only when she began to look continuously at any object, but after a little time there was confusion in both eyes alike. The defect in vision was confined to near objects. She could easily tell the time on a church clock three eighths of a mile away. As time wore on many of her disagreeable sensations disappeared after a night's rest, and reappeared the following day after fatigue. More than five years have elapsed since the attack, during which time the return of health has been gradual, and is not yet complete.

Bromide of potash seemed to give more relief than any other medicine. Rest and a careful avoidance of excitement, with favorable positions of the body, constitutes the plan of treatment.

CASE II. In the early part of September, 1879, I was called to attend Mr. E. D., aged fifty-seven years, temperate, healthy, and of more than average intellectual force and activity, a manufacturer of edged tools. He was lying upon his right side on a sofa, and seemed in his ordinary robust health. He gave the following medical history: The day previous he went fishing upon a small lake; the day was hot, and he suffered a good deal both from reflected sunlight and heat. On his return he felt he had somehow been injured by the unusual exposure. He had, however, a fairly comfortable night's sleep, but on attempting to rise in the morning he fell from an attack of vertigo. "He felt as though he was flying all to pieces," but soon learned that so long as he kept his face to the right of the median line he had no return of his dizziness, but the moment he turned his face to the left the vertigo and unconsciousness returned. He could rise from his bed, walk about, stoop, and perform a variety of motions provided he never rotated his head to the left. There was but slight disturbance of his intellect. He could plan his business, but memory did not bring him the details quite as quickly as usual.

He complained of a continued and disagreeable sensation in the left side of his head, which he could not describe. It commenced in the centre of his forehead, and extended across the left parietal region to the centre of the occiput about on a line with the top of his ear. The affected side seemed heavy, "as though filled with lead," and a continued exertion of the will was required to keep the head erect. There was no paralysis, acute pain, or tactual perversion. I could not compare his pupils, as the right one had been injured by an accident. Eyes sensitive to light, sunlight or lamplight was painful; pulse, temperature,

and respiration not far from normal; appetite diminished. No marked change in the symptoms occurred during the two following days. Two or three days after the attack, while lying on a sofa on his right side, as he was wont, he felt as if lifted into the air, then dashed to the earth. What did happen is not known, as he was alone at the time, but when consciousness returned he found himself upon the floor. At times he felt death impending, material things seemed fading away. These distressing sensations gradually decreased during the next ten or twelve weeks. His appetite returned, sleep was restful and undisturbed provided he slept with his head well elevated. At no time was there acute pain, nor were the scalp or other soft parts of the head abnormally sensitive to touch. At the present time, June 28, 1881, he states he has a disagreeable sensation in the left parietal region, which does not interfere with ordinary mental labor. Since his attack in 1879 he has suffered from conjunctivitis of the left eye, and once from iritis, with cerebral symptoms of a mild type. The sight of the left eye has failed a good deal during the past year.

Treatment, as in all cases not based upon well ascertained pathological conditions, was mainly empirical. Bromide of potash appeared to give the most relief in the early stage of the disease. Quinine and other remedies were tried without satisfactory results. A careful avoidance of circumstances which tended to increase the vertigo or disturb the functions of the brain and nervous system was advised, with rest and quiet.

CASE III. The subject of the following medical history is a stout, robust man, weighing two hundred pounds, fifty years of age, a manufacturer, who was struck by a moving railroad train, thrown into the air, and fell vertex downward upon a pile of railroad iron. The blow was received upon the left parietal and vertical region, the scalp was torn downward from the left side of his head, the periosteum was separated from the greatest convexity of left parietal bone and lay in a fold on a line with the attachment of the ear. The anterior margin of left parietal was slightly depressed, although no linear fracture was observed. There were other and severe injuries, as fracture and displacement of sternum, fracture of ribs, also of spinous process of vertebra, of which I do not now propose to speak, which required a fixed dorsal position for several weeks. There was frequent vomiting, complete paralysis of bladder, partial paralysis of lower limbs, and other symptoms of injury to the brain of a severe character. During the first three weeks pulse and temperature ranged a little above a hundred. His consciousness of passing events was unimpaired, and all the faculties of the mind seemed in normal activity and force, yet he had a duality of perception of all persons and other material things. Two trains of thought were present, each struggling for precedence. One consciousness perceived in a clear and normal manner, and processes of reasoning could be carried on correctly by a firm exercise of the will. There seemed a second consciousness which was continually perverting the truth and leading him to realms of fancy, inconsistencies, and trouble. He had dual vision. Two doctors attended him, both of the same name but different in character. One was pleasant and attentive, the other cross and disagreeable. Both came and went at the same time, but there was no other agreement between the two. He had two throats, one well, the other sore. The sore throat was continually complain-

ing that the well one did not do all the swallowing. This duality haunted him for several weeks and then gradually disappeared. At this period of his illness he first began to move his head, and now discovered that any rotation of the head to the left of the median line was instantly followed by intense vertigo, and loss of consciousness. Careful and oft repeated experiment taught him that a movement of the head to the left of the median line brought unconsciousness so quickly it was impossible to avert it by a counter movement. Nausea and vomiting were frequent concomitants, with a sensation of approaching dissolution. It was impossible to know exactly how much his convalescence was affected by the cerebral trouble. It was certainly much retarded by an abundant effusion of bloody serum into the right chest. In seven months from the accident he began to take some charge of his business affairs; but any mental activity, especially in the line of mechanics, was sure to be followed by an increase both in the frequency and severity of the attacks of vertigo. A hypodermic of one fourth gramme of morphia, immediately after mental work, would ward off an attack as well as give refreshing sleep. The effects of this hypodermic would last for two days, when it was repeated. As this peculiar form of vertigo gradually disappeared, new and troublesome disturbances in memory took its place, of a similar type, namely, if he was conversing with a person upon his right, and a second person should approach him on his right, for conversation, on attempting to renew conversation with the first party all memory of events while the head was turned to the left would be lost; it might recur in an hour, or never. But should the converse happen no difficulty in renewing the train of thought would occur. Another prominent symptom was sleeplessness. The longer it was protracted the more frequent and violent were the attacks of vertigo. His eyesight, previously very strong, is now much impaired. It is proper to add that after the acute stage had passed the temperature was uniformly from half to a whole degree below normal.

A satisfactory explanation of the symptoms in the cases reported above is a difficult problem to solve. I find nothing parallel to them in the books, and it is with some hesitation that I offer the following as the only rational solution which occurs to me, from present reading and personal observation. In the case of Mr. Leonard I think we have a key to the problem. Let us recapitulate. In his fall Mr. R. received the whole weight of his body, (two hundred pounds) on the left vertex and parietal region of the skull. If the skull were very brittle we should probably have fracture with concussion, if elastic, the force of the blow would fall more directly upon the brain, and contusion and concussion would both be present. There was depression of the anterior parietal bone, but no linear fracture observed. It is, however, probable that some atomic separation of the inner table occurs in all cases of depression. In concussion we have for its pathology "intense redness of the pia mater with flaxion or dilatation of the brain capillaries." In contusion we have the same condition, with perhaps other and more serious pathological changes. We should thus have traumatic cerebral hyperæmia mainly confined to the injured hemisphere. Gray states "that the walls of the cerebral veins are remarkably thin, and muscular fibres are entirely wanting." They are also without valves. "The internal jugular vein drains the blood

from the interior of the cranium, and is itself without valves except at its outlet. As it emerges from the brain at the base of the skull, it soon passes under the platysma and sterno-cleido mastoid muscles, passing downward, and, unlike its fellow, crosses over the internal carotid, which acts as a bar across the internal jugular. Thus, when the head was rotated to the left it would temporarily dam up the jugular, checking the flow of venous blood through all its ramifications, giving us *unilateral cerebral hyperæmia* of the left hemisphere in a system already in a condition of fluxion. Nothnagel states that venous hyperæmia of the brain will always attend any interference with the passage of the blood through the jugular veins. In Ménière's disease, or labyrinthine vertigo, from lesions of the semi-circular canals of the middle ear, Woakes says the vertigo is caused by hyperæmia of the ampulla and the extremely delicate membrane lining the canals. Nothnagel, Hammond, and others give "vertigo" as the symptom common to all cases of marked cerebral hyperæmia.

The consideration of *unilateral hyperæmia* of the brain naturally leads to the question, Are the two hemispheres alike in functions, the one being a duplicate of the other? From all the facts bearing upon this interesting question which have come to my notice, I am led to believe that so far as the falx cerebri separates the brain into two distinct parts, each hemisphere above the corpus callosum is the duplicate of its fellow, each carrying on the functions peculiar to its structure; in health acting in perfect harmony, in disease, under some circumstances, either one performing the work of both while the functions of its fellow are held in abeyance. In proof of this, Cruveilhier cites a case of hemiplegia of long standing, in which the whole of one hemisphere was atrophied, yet none of the functions of the brain were wanting. One hemisphere has been wounded by a pistol ball, and no disturbance of the intellect has been observed. In disease, I believe the functions of one hemisphere may be perverted, as in the case of Mr. L., by the sequel to traumatism, and the diseased hemisphere give rise to vagaries, which the hemisphere in health may, or may not, be able to control.

Since the above notes were written Mr. L. has experimented upon turning the head to the left, with the following results, namely: if he takes a position of ease, in a reclining chair, rests his head upon the back and slowly rotates it one eighth of a circle to the left, he quickly feels an uncomfortable fullness and pressure at the left of the vertical region, the functions of the brain become gradually arrested or perverted in the following order: inability to formulate sentences; inability to express any idea in words; soon complete unconsciousness. A repetition of the experiment produces distress and vertigo, and a sense of impending danger deters from further observation, the effects of which are continued for many hours.

In the last two cases the sun's rays greatly aggravated all the uncomfortable sensations, confusion of ideas supervened, and all business transactions required to be suspended.

In closing, I will say that all the parties named above are living and may be consulted at pleasure.

— We are glad to learn that the National Board of Health is taking steps to secure the vaccination of all emigrants before their embarkation for this country.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAYEN, M. D., SECRETARY.

MAY 28, 1881. Ninety-four members present. Dr. R. M. HODGES in the chair. The following communication from the committee of supervision was received.

"The committee of supervision unanimously recommend to the Society that the number of general meetings be less frequent; they believe this to be necessary in order that there may be a better opportunity given for sectional work. They therefore present the following resolution:—

"*Resolved*, that in addition to the stated and annual meetings there be held annually but two meetings for medical improvement, namely, on the last Saturday of December and the last Saturday of February."

On motion of Dr. G. C. SHATTUCK, seconded by Dr. J. J. PUTNAM, the report of the committee was adopted.

MUSCULAR ATROPHY.

Dr. J. J. PUTNAM showed an unusual case of muscular atrophy, affecting a young man of seventeen years, of healthy parentage, and otherwise himself in good health. The muscles principally involved were the *senatus*, the *biceps* and *forceps*, the *deltoid* (in its anterior portion), and the *latissimus dorsi*, all symmetrically. The muscles of the face, especially on the right side, were also somewhat affected, giving a peculiar stiffness to the motions of the lips, and impairing the closure of the right eye. The straight muscles of the back and some of the muscles of the legs were also slightly atrophied. On the other hand, the muscles of the forearms and hands and the *infraspinatus* scapulae were immensely developed and strong, suggesting true hypertrophy. The progression of the disease had been very slow; there was no fibrillary twitching, and the faradic reactions were everywhere fairly good. The patient stated that so far back as he could remember he had been slow and awkward in all his movements, but the marked atrophy was of about four years' date. Dr. Putnam stated that the case probably belonged in the group of hereditary progressive muscular atrophies, though differing from the typical forms. There was no hereditary taint, nor were other members of the family similarly diseased.

Dr. H. I. BOWDITCH read a paper entitled,

THE MEDICAL EDUCATION OF WOMEN.

In conclusion he offered the following resolutions:—

Resolved, That this society recommend that licenses to practice physic in Massachusetts be hereafter given by the censors of the Massachusetts Medical Society to those women, who, upon an examination similar to that given to men, are found equally proficient.

Resolved, That with such licenses should be given all the rights and privileges granted to men except those of attending the meetings and of voting upon questions involving the organic laws of the society.

Resolved, That to each district society and to the general society should be left the question of extending an invitation to female licentiates to attend their respective meetings.

Resolved, That in the opinion of the Suffolk District Medical Society it is desirable for Harvard University to give medical instruction to women.

Resolved, that the secretary of this society be directed to send copies of these resolutions to the councilors of the Massachusetts Medical Society, and to the Society itself at their next meeting, and likewise to the president and corporation of Harvard University.

In the discussion which followed Dr. G. C. SHATTUCK said that he had listened attentively to the remarks of his friend, Dr. Bowditch, as he always did to whatever his friend had to say. As Dr. Bowditch had invited those differing from him to try to look at the matter from his point of view, he would ask reciprocity from Dr. Bowditch, who had accused Harvard University and the Massachusetts Medical Society of being guilty of gross dereliction of duty in declining to instruct and admit women as Fellows. Dr. Shattuck was the dean of the medical faculty some thirteen years ago, when two women applied for admission to the university. He had seen these women repeatedly in reference to their application, and was present when it was made to the medical faculty. He had also been present at meetings of the Massachusetts Medical Society, and at those of the councilors when the admission of women was proposed and discussed. The result of careful consideration and investigation was to confirm him in the opinion that the university and the society had acted in strict conformity with righteousness and justice when the one had declined educating women, and the other had refused admitting them as Fellows of the Massachusetts Medical Society. Surely right and duty go together, especially in matters concerning our fellow creatures. Each one of us is responsible to God who made us for employing wisely the faculties and talents given us. It was said in derision of a distinguished English statesman that such was his conceit that he would undertake at an hour's notice the duties of a prime minister, an archbishop, a field-marshal, an admiral, or a surgeon, or a councilor at law. Now, have I a right to command a line-of-battle ship, or to argue a question of law and jurisprudence, when nature has denied me the faculties which with training and education only might be sufficient for the discharge of the duties? There are those who esteem women very highly, and admire them very much, who do not think that the God who made them has given them an organization as well adapted to the practice of medicine as is that of the other sex. They know of no reason why, since the creation, this profession and art should not have been given up to or shared with women except their organization be less adapted to the discharge of the duties. There have always been exceptional cases—women with peculiar faculties and structure, who have practiced the art of healing in some or all of its branches—these are not numerous enough to make it worth while for the university to construct lecture-rooms and laboratories for their peculiar use. It is not considered consistent with good morals for young men and young women to dissect naked bodies together, or to discuss matters pertaining to the physiology and pathology of the reproductive organs. An idea prevails with many in the community that women mentally, morally, and physically are as well fitted to practice medicine as men. There are many members of the Massachusetts Medical Society who regard this idea as a dishonor, inseparably connected with harm and mischief, and that it

is emphatically our duty to oppose and correct such erroneous ideas.

The precise question before us is, shall we recommend examining and giving certificates to women by the censors. By the act of incorporation, the holder of such a certificate must be admitted to the society. By our act of incorporation our duties of examination and admission are restricted to men.

There are those of us who think our predecessors knew what they were about and acted wisely in this matter, and that now men are men, and women are women, as they were a hundred years ago. It is admitted on all hands that a great many imperfectly educated and incompetent women are practicing medicine in this community, and shall we improve our Society by admitting many of these into it. Many of us who have studied this matter are convinced that other State societies have suffered very much in this way.

But, Mr. President, I do not intend arguing this matter; in conclusion I will only express the conviction that those who this evening say no to the measure proposed by Dr. Bowditch, do so after careful study and investigation, and with a high appreciation of their duties as members of this society, and to the community in which we live.

DR. BOWDITCH said that he did not agree with Dr. Shattuck in his interpretation of the laws regarding the admission of licentiates, but in order to remove any possible objection he would substitute the words "certificates of due qualifications" for the word license in Resolution I.

DR. CHADWICK spoke of the attitude of other State societies in regard to the question of admitting women. These remarks were reserved for separate publication as a paper.

DR. MARCY, in discussion of the question, advocated the admission of women to the membership of the society and the full privileges of education at Harvard.

It is a fact that over one hundred women are in the practice of the calling of the medical art in the city of Boston alone, more than one eighth of the entire number of all the various professors of medicine. Thus it will be seen that it is not a question of inviting or encouraging women to become a practitioner of medicine, but the rather since she has determined to assume this position of great responsibility, that we do not refuse to her the best possible opportunities to prepare herself for this vocation. The question ceases to be one of sentiment or preference, but of fact. It cannot be believed that female practitioners are to be so large an element in the society as to cause the controlling interest of a great profession to be delegated to the female sex.

Woman has shown herself so eminently fitted for the vocation of teaching, that it is probably true that nine tenths of the present generation have been in great measure trained by her. The problem does not hold good in medicine, where the devotee to science must be a life member. The fundamental law controlling the sexes, marriage, maternity, home, is as immutable as that of sexuality itself, the present age to the contrary notwithstanding, and the successful female practitioner will be the exception and not the rule. The human mind is so constituted that much is developed by opposition itself. History declares this to be true in reference to religious intolerance. "The blood of the martyrs is the seed of the Church." Homœopathy has grown under the fostering care of the opposition of the Massachusetts Medical Society, until, stimulated by the cry

of intolerance, ostracism, martyrdom, this most delusive of all delusions has now its head centre of power and influence in Boston itself.

We owe it to this same undue conservatism that the medical department of Boston University is homœopathic, and most of us are aware that upon the Continent, where homœopathy has been allowed to rise or fall upon its simple merit, it has no place in university teaching and is already nearly obsolete. The parallelism here holds good. The practical difficulties of teaching woman medicine are more imaginary than real. Nearly all the universities of Europe have opened to her their doors upon equal privileges. The few women who have entered the lists and are determined to pay the price of success in a self-sacrificing life of devotion and labor, should be granted every privilege, and then without flattery or favoritism be tested in qualifications as men. At present we are practically driving every woman who would be a physician into quackery. A large number of the students of the Boston University are women, not because they desire to be homœopaths, but because it is the one place where woman is welcome to a free rivalry in medical study.

We all, as true sons of Harvard, welcomed the change and aided in her support, when she led the van in the movement for a higher medical education. Guided by grand conservatism of learning and wisdom which would recognize any change which meant true progress, let her open her doors to medical students regardless of sex, and the good sense of the profession will not be wanting in giving her cordial support. Governed by simple justice and judicial wisdom this society will adopt these resolutions by a large majority.

DR. G. H. LYMAN wished to protest against forcing upon the society an element which was obnoxious to at least one half its members, and for no other reason than to assert a mere abstract right, as its advocates chose to consider it, and the unnecessary assertion of which, unless by an overwhelming majority, would only bring discord into a society where it was essential harmony should prevail, in view of the quackery which was awaiting us from all sides.

After some further discussion, the previous question was moved and carried. The main question being put as to the adoption of the resolutions, it was decided in the negative.

REPORT OF THE MIDDLESEX SOUTH DISTRICT SOCIETY TO MASSACHUSETTS MEDICAL SOCIETY.

BY HORACE C. WHITE, M. D., REPORTER.

ARTICLE XII. of the by-laws of the Middlesex South District Medical Society reads: "The reporter shall prepare and present at the annual meeting of the State Society a report on cases of importance in the district, the public health thereof, or any subject of local interest connected with practice of medicine or surgery."

Under the date of April 22, 1881, the secretary sent to each member of the society a postal card which read as follows: To facilitate the work assigned to the reporter by by-law XII, fellows are requested to make their annual returns of important cases, prevalent diseases, etc., on or before May 10th, to Dr. Horace C. White, Somerville, Mass.

Up to May 18th, in compliance with that request, I had the honor to receive only one communication, that

from the president of the society. I then made a personal appeal to some fifteen or twenty physicians in different parts of the district, and received quite a number of excuses and apologies, and a *few very short* reports. This scanty material and the little time I have been able to give is my apology for a hasty report; my faith in the benefits that would accrue from a proper report from each district is my apology for any report under the circumstances.

So far as I have been able to learn, there has been no severe epidemic during the past year, and the life of the physician, although it may have been busy, has not been unusually eventful. The sickness rate generally has been high in proportion to the death rate, or in other words, diseases have generally been of a mild type.

I have no cases of importance to report; I will mention, however, what Dr. Hosmer is pleased to call "leg vaccination." It has been his custom for nearly ten years, on the eighth day of a successful, ordinary arm vaccination with a single insertion to puncture the vesicle and insert some of its contents into the child's leg. This practice is a compromise between the method of multiple insertion advocated by many modern vaccinators, and the practice of repeated vaccination recommended in the early days of the discovery. He has succeeded in a percentage higher than he has ever before known. He says, "I believe in it, and when the secondary insertion counts so many 'takes' as it has this winter, I am glad to have done it." With regard to prevailing diseases my reports are not full.

The fact that they have generally been in mild form is a reason why less attention has been given to the details of cases. In many instances physicians have seen so little of the majority of the cases that they cannot note the whole course of the epidemic.

Scarlet fever has prevailed in mild form. The number of cases reported to the Board of Health of the city of Cambridge, for the year 1880, was ninety-two; number of deaths five. In the city of Somerville for the same time, the number of cases reported was forty-three, and number of deaths six.

Diphtheria has generally been of mild type, and although constantly present in the early part of the winter, the whole number of cases was not large, and they were mostly confined to children. Dr. Hosmer reports a case of recovery in a boy sixteen (16) months old who was afflicted with the laryngeal form of the disease. Tracheotomy was *not* performed. In Malden, however, the disease has been universally prevalent. Dr. Shute reports, "Diphtheria caused nearly twenty-three per cent. of the deaths of the year. Since January, there has been a decided abatement of the ravages of the disease. The majority of cases can easily be referred to defective drainage, foul cess-pools, etc., as a cause." Number of cases reported during 1880 in Cambridge was one hundred and ninety, deaths thirty-eight; in Somerville, cases one hundred and eight, deaths nineteen.

Pneumonia has prevailed to an unusual degree in Everett, Arlington, and Somerville. Dr. Wakefield, of Everett, has never seen so many cases in any six months for the past twenty-eight years. Dr. Hodgdon, of Arlington, has seen more cases than ever before in the same time, while in Watertown and other places but few cases are reported.

Measles, genuine and German (rubeola and röteln), have prevailed quite generally in a mild form,

but have failed in an unusual way to conform to a constant type. There has been much variety both in regard to the duration and intensity of the symptoms belonging to the first stage and also to the amount and rapidity of the march of the eruption. Dr. Morris, of Charlestown, has observed quite a number of second attacks of rubeola in the same individual. One child had the disease *well marked* twice inside of three months. Dr. Wakefield, of Everett, says: "Rubeola has prevailed as epidemic; our public schools were thinly attended in February and March." Dr. Hodgdon, of Arlington, says: "Röteln was very prevalent in January, February, and March, and in April and May we had a good deal of measles." Dr. Hosmer, of Watertown, says: "Measles, both genuine and German, have prevailed to an extent unknown in many previous years. Genuine measles first appeared in December, 1879, and obtained their greatest prevalence in the latter part of the winter and even now new cases are cropping out. Röteln did not come to my observation earlier than midwinter, and the cases have not been numerous. Repeatedly rubeola and röteln have shown themselves in the same individual in a short interval but without a constant order of succession."

In Somerville, during the past winter, we have had a large number of cases of both diseases. In quite a number of cases there were second attacks; or one disease followed the other with considerable regularity with an intervening period of six weeks or two months. Several of these cases have seemed to be typical cases of rubeola in both attacks.

The question which naturally arises is, Have these two diseases a pathological identity? Or what relation do they bear to each other? In looking over the literature of measles I find the following items bearing upon the subject:—

Rubeola, measles, derived from rubeo, to be red. This word appears to be of Spanish origin and probably emanated from the School of Cordova; it was formerly written rubiola. Another term by which this affection has been designated is Morbilli, or minor plague, being the diminutive of *il morbo*, as the Italians called the plague. The restrictions now adopted in the application of the term rubeola are of rather modern date and owe their establishment to Sanvages, before whose time great confusion prevailed in the naming of several of the exanthemata; rubeola in particular was used to signify equally scarlet fever and measles. A similar inaccuracy was to be found among French writers also, for the word "rougeole," their common name for measles, meant at one time scarlatina, and that so decidedly that it was thought necessary to apply distinct names to the two diseases in consequence of the difference between them becoming fully understood. Chevenau informs us that the Marsellais used the word rougeole to signify scarlatina, and distinguished measles by the name of senapion.

In our country Morton maintained the identity of these exanthemata, and considered the relation existing between them the same as between distinct and confluent small-pox. Even so recently as 1769, Sir William Watson confounded the two diseases. The correct diagnosis between them ought probably to be referred to the time of publishing the second edition of Dr. Withering's Essay on Scarlet Fever, in 1793.

Sennertus in the middle of the seventeenth century discussed the question, "Why the Disease in some

constitutions assumed the form of small-pox and in others of measles."

Drembrock, in 1687, says: "Small-pox and measles are only different degrees of the same affection." The same doctrine was still more recently maintained by Lange, a professor of Leipzig. The general law of measles, in common with other of the exanthemata, is that they affect the system but once. Dr. Thomas, in his works, published in 1813, says: "Like the small-pox, when genuine, the measles never affect persons but once, their contagion appearing to be of a specific nature." By some of the older authors its occasional recurrence was admitted, but of late years the fact has been most satisfactorily established. Dr. Baillie has described eight instances of the kind, and it is a singular circumstance that they occurred in individuals of the same family.

In Dr. Willan's cases, which occurred in his own family, the disease was taken a second time in two individuals. Bursorius and Morton also relate instances of its appearance a second time. Dr. Willan has thrown out the suggestion that *when there are no catarrhal symptoms the susceptibility of the disease is not removed*. He states that the disease occurs sometimes in another spurious form, which is *also insufficient to protect the system from future attacks*, as many persons thus affected, who had the febrile, catarrhal, and eruptive symptoms, took the disease a second time.

Dr. Thomas, in speaking of an epidemic in New York in 1812, when the measles were very prevalent there, says: "It appears, however, that spurious forms of the disease, insufficient to protect the system from subsequent attacks, occur in a manner analogous to the spurious appearance of small-pox and variola vaccinae."

In Dr. Good's work, published in 1823, he divides measles into three varieties: vulgaris (common measles), incoeta (imperfect measles), and nigra (black measles). He describes the second variety as follows: "Rash running its course with little fever or catarrhal affection, *affording no certain security against the common or regular disease*. This has been called usually, and especially by German writers, spurious measles, but as it occurs most frequently when genuine measles are epidemic, and is *doubtless a result of their contagion*, it is less properly a spurious than an imperfect or immature rubella. I have hence exchanged the term spuria for incoeta."

Dr. Willan denominates it "rubeola sine catarrho," but as the genuine measles themselves, capable of affording emancipation, have sometimes appeared with *very slight* catarrhal symptoms, incoeta seems preferable. "Some," says Dr. Heberden, "have been so fortunate as to have the measles appear, often suffering so very little from fever or any of the preparatory symptoms that they could hardly say that they had been ill. In this case the constitution is protected by a natural insusceptibility of the disease, which is the best protection we can possess. In the case of imperfect measles it is only operated upon by some temporary influence, and hence as soon as this influence ceases the common susceptibility returns. For many persons, who on former occasions of the measles prevailing, and after exposure to their contagion, have exhibited certain *irregular appearances* of febrile, catarrhal, and eruptive symptoms mistaken for the true disease, were afterwards attacked with measles in an exquisitely genuine form."

Dr. Willan later mentions having seen other cases where the efflorescence without fever or catarrhal symptoms having declined, there appeared on the fourth day from its commencement a new efflorescence and violent disorder of the constitution.

From these items and a large number of others of similar nature running through the medical literature of the past, and from as careful a canvass of the symptoms of the so-called r  theln or German measles, as it has shown itself during the past year, as its trifling nature will allow, I have been unable to distinguish it as a new disease, but rather as an irregular or imperfect form of rubeola, occurring while that disease was epidemic or at the invasion of an epidemic, following the rule of all exanthemata that during the prevalence of an epidemic, and particularly at its beginning, the prominent characteristic of the disease shows itself in modifying even minor diseases.

At least it will require more careful attention before we shall be able to speak of it as anything but the *so-called* German measles.

— *London Truth* says: "The figures of Dr. Buchanan, the medical officer of the local government board, in regard to small-pox are remarkable. He estimates that during the last twelve months 1532 persons have died of small-pox in London. Of these, 325 had been vaccinated, and 637 had not, while it was not known whether the remainder had been vaccinated or not. It would appear, therefore, that vaccination reduces the chance of dying of small-pox by one half. Against this, however, is to be reckoned the very considerable number of persons whose health is seriously injured by impure lymph. That the present law, obliging all children to be vaccinated, requires modification is shown by the fact that the parents of rich persons never allow their children to be vaccinated with the lymph which is considered good enough for those of poor persons. Every one knows that when a child of wealthy parents is to be vaccinated some medical man is chosen who either has obtained the lymph direct from a cow or from a very healthy child."

The child of poor parents in Boston is on an equality in this particular with all others.

— The following communication to a daily contemporary is a pretty fair sample of one of the consequences of the crime at Washington:—

"During the Mexican war I was an Ohio volunteer, and during a skirmish near the city of Vera Cruz was shot between the eleventh and twelfth ribs, and half of my liver carried away. After my recovery from the wound I enjoyed better health than previous to the disaster. During the war of the rebellion, while a member of an Ohio regiment, and at the battle of Arkansas Post, I was shot between the tenth and eleventh ribs, and the remaining half of my liver disappeared. After recovery I was a better man than ever; in fact, I never knew what perfect health was till I lost my liver. My case would seem to prove, and I believe such to be the case, that the liver is a mistake of nature. The most singular part of my case is that neither the balls nor the liver have ever been found."

Medical and Surgical Journal.

THURSDAY, AUGUST 4, 1881. 2

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE INDEX CATALOGUE, VOLUME TWO.

THE continued contemplation of the first volume of the Index Catalogue of the Library of the Surgeon-General's Office, United States Army, in its honored place among our books of reference, has perhaps somewhat diminished the feelings akin to awe with which we greeted its appearance. The respect for the stupendous work and its compilers has by no means decreased, however; familiarity has brought increased regard rather than contempt, and we welcome the second volume as an earnest of the continuance of the good work so nobly begun.

If our army is not impressive by its numbers it is certainly foremost in the arts that pertain to peace, and its medical department deserves and receives the thanks of the whole medical world for its various publications, of which the Index Catalogue is but one.

The notices of the first volume in foreign journals have been particularly cordial and appreciative, and serve to show that the pride with which we speak of the matter is not due to blind love for things American.

The present volume contains in round numbers a thousand pages and carries the index to the middle of the letter C. As Dr. Billings tells us in his short note to the Surgeon-General, which serves as preface, the volume contains 12,459 author-titles, representing 4,934 volumes and 9,810 pamphlets. It also includes 11,550 subject-titles of separate books and pamphlets, beside — and this is the feature which deserves especial mention and is the peculiar characteristic of the *Index Catalogue* — 37,310 titles of articles in periodicals. At least one of the many notices of the first volume leads us to fear that the full scope of the work is not as yet everywhere appreciated, and leads us to feel that it may not be improper to again say that the Index Catalogue is not merely a catalogue of the very large medical library of the Surgeon-General's office, but is also an index to the various articles in the very complete files of the numerous periodicals and reports which belong to the library, so that under the head of Chlorosis, for instance, we have first a catalogue of the various books and pamphlets on the subject, and afterwards an index to the various articles on the same subject scattered through the various journals. Twelve pages are filled with additions to the long list of medical periodicals and the abbreviations of titles em-

ployed in indexing, which was given in the first volume.

Catalogues cannot be considered interesting reading, but to one who loves the objects catalogued there is enjoyment to be found in contemplating the long array of names, and every one who loves and uses medical books, and especially those poor souls who find something of a miser's pleasure in their possession, will look through these crowded pages with delight. A careless turning of the leaves brings out a few interesting items which might perhaps be classed as curiosities of medical literature. The Brain fills eighty-two pages, the Body fills three and a half pages, while the Cadaver extends to fifteen, and the Bones to twenty-four pages. The different editions of the various publications of Sir Benjamin Brodie cover nearly a column, or half a page.

Under the name of Richard Bright occur but five short sub-titles, while Bright's Disease follows after, dragging its slow length through eight and a half long pages; "if a doctor has the luck to find out a new malady it is tied to his name like a tin kettle to a dog's tail, and he goes clattering down the highway of fame to posterity with his æolian attachment following at his heels," ever growing as it follows.

Under the list of works of William Cheselden, which includes his *Osteographia* and *Treatise on the High Operation for Stone*, reference is made to Douglas (John), *Animadversions on a late pompous book, intitled Osteographia*, and to Houstoun R. "Lithotomus Castratus; or Mr. Cheselden's treatise on the high operation for stone, thoroughly examined and plainly found to be Lithotomia Douglassiana (etc.), under another title; in a letter to Dr. John Arbuthnot, in an appendix, wherein both authors are fairly compared; to which is added a word of advice to surgeons." Mine enemy's book and my bitter review are here in one "red burial blent."

Of course the usefulness of the index will increase with each succeeding volume, and we can only repeat the wish that Congress will continue its liberality that the volumes may follow each other in rapid succession. We feel assured the great work, so long in preparation and so eagerly looked for by medical scholars, will in due course of time be completed.

THE INTERNATIONAL MEDICAL CONGRESS AT LONDON.

THE International Congress at London is, as we write, already in actual operation, and the plans and preparations of many past months are being tried by the test of a week's professional conference and social entertainment of more than two thousand delegates from various parts of the world. The United States is numerous and well represented. A distinguished delegate from this country, Dr. Billings, of Washington, is one of the vice-presidents, and he is also expected to deliver the address at the third general meeting, the subject being Our Medical Literature.

Elsewhere will be found the regular programme

for the different days of the week's session, the whole concluding with a dinner at the Crystal Palace. In addition to the regular programme the secretary-general furnishes a list of the various places of interest which may be visited by members of the congress under especially favorable conditions, of the clubs offering their hospitality to foreign members, and of excursions open to limited numbers.

The whole offers a striking example of the marvelous resources of such a place as London, and of the great variety of interests with which she tempts the stranger on such an occasion. What is lost thereby, and somewhat probably will be, in devotion to scientific discussion, will doubtless be gained in other ways, if not more profitable, at least no less refreshing. The congress will be immediately followed by the annual meeting of the British Medical Association. Many of the foreign visitors, it is expected, will remain for the second medical feast, but a thorough and profitable enjoyment of both will require a strong professional digestion with a rapid assimilation, and it can scarcely be otherwise than that the *éclat* of the first week should obscure to some extent that of the second.

THE NEW YORK FOOD AND DRUGS ADULTERATION LAWS.

We publish in another column the text of the new law in New York to prevent adulteration of food and drugs. Attention was called to it in our New York notes last June, when it received the governor's approval, but a want of space has hitherto prevented our giving the provisions of the act in full, which the importance and difficulty of the subject and the apparent merits of the act itself induce us to do. The same law goes into operation in the State of New Jersey also. Its passage was largely secured through the persistent and energetic activity of the *Sanitary Engineer*, the provisions of the act being drawn up by the experts who were appointed by the National Board of Trade to award the prizes offered by the *Engineer* for the best essays on the general subject of the adulteration of food.

It will be seen that the efficiency and enforcement of the law will depend very greatly upon the State Board of Health, the composition and organization of which is at present supposed to be equal to these new duties. Should politics or a distribution of places at any time lead to new experiments with the organization of the Board of Health the operation of the law to prevent adulteration might not be found to respond to the wishes of its framers.

MEDICAL NOTES.

—Thirty-two thousand three hundred and ninety-two patients were treated by the Marine Hospital Service during the fiscal year ending June 30, 1881.

—We are pleased to see that a pathologist has

been appointed at the Boston Lunatic Hospital. This is a step in the right direction. Dr. W. W. Gannett, the appointee, is well qualified for the work, upon which he has already entered.

—The thirty-second annual session of the Medical Association of Georgia was held in Thomasville on April 20 and 21, 1881. The following are the officers for the ensuing year: president, William F. Holt, Macon; first vice-president, Eugene Foster, Augusta; second vice-president, T. M. McIntosh, Thomasville; secretary, A. Sibley Campbell, Augusta; treasurer, K. P. Moore, Forsyth. The next session will be held in Atlanta, on the third Wednesday in April (19th) 1882.

—There was a very large attendance at the fourteenth annual meeting of the American Otological Society held at Newport, R. I., July 26th. Morning and afternoon sessions were held. Papers were read as follows: Suggestions Regarding the Treatment of Suppurative Otitis, by Dr. S. Theobald, of Baltimore; On the Value of Operations in which the Tympanic Membrane is Incised, by Dr. D. B. St. John Roosa, of New York; On the Tuning Fork in Diagnosis, by Dr. D. B. St. John Roosa; Removal of a Foreign Body by Disarticulation of the Auricle, by Dr. J. Orne Green, of Boston; On Malignant Growth in the Posterior Nerves, with Early Aural Symptoms, by Dr. C. H. Burnett, of Philadelphia; A Case of Epithelioma of the Middle Ear, by Dr. C. J. Kipp, of Newark; Selections of Test Words according to their Logographic Value, by Dr. C. J. Blake; Sudden and Complete Loss of Hearing in One Ear During an Attack of Mumps, by Dr. A. H. Buck, of New York; Small Vascular Tumors in the Membrane Tympano, by Dr. A. H. Buck. Dr. Samuel Sexton, of New York, and Dr. R. C. Brandegee, of New York, were not able to present the papers which they intended, and they were exchanged. The following officers were elected for the ensuing year: president, Dr. J. Orne Green, Boston; vice-president, Dr. J. S. Prout, Brooklyn; secretary and treasurer, Dr. J. J. B. Vermyne, of New Bedford, Drs. C. J. Blake, and J. Orne Green, of Boston; committee on membership, Dr. John Greene, of St. Louis, Dr. H. G. Miller, of Providence, Dr. C. H. Burnett, of Philadelphia.

—A medical paper at Leipsic has been fined one hundred marks and costs at the suit of seventy-five homeopathic doctors, for publishing a lecture delivered to a Berlin medical society, in which homeopathy was denounced as quackery and swindling.

—Messrs. Wm. Wood & Co. have availed themselves of the excuse of the daily provisional programme of the International Medical Congress at London to present to its delegates a list of their numerous medical publications. The pages are elegantly bound in red silk covers, and the whole presents an appearance very creditable to the enterprising firm from which it emanates. We are glad to be able to recognize and appreciate enterprise and skill wherever shown.

—Under authority conferred by the sundry civil appropriation bill, the secretary of the treasury has

appointed James Law, of Ithaca, N. Y., James H. Sanders, of Chicago, and E. T. Thayer, of West Newton, Mass., a commission to be known as "the treasury cattle commission." The duties of the commission will be to investigate all cases of the disease known as pleuro-pneumonia in neat cattle which shall be reported to it, especially along the dividing line between the United States and Dominion of Canada, and along the line of transportation from all parts of the United States to ports from which cattle are exported, and to perform such other duties as may from time to time be prescribed by the secretary with reference to the disease, in order that cattle shipped from ports of the United States to foreign ports may be known and certified to be free therefrom. The commission has been instructed to meet as soon as convenient, for the purpose of adopting such regulations as may be deemed proper. The compensation of the members of the commission when actually engaged will be ten dollars each per day and actual necessary expenses.

NEW YORK.

—There has probably never been a season when so many New York physicians have gone abroad as the present, and most of them are to be delegates or visitors to the International Medical Congress in London. The New York Academy of Medicine will be represented at the congress by its president, Dr. For-dyce Barker, its corresponding secretary, Dr. John Adams, and its treasurer, Dr. Horace P. Farnham, besides a large number of other Fellows.

—A committee of the State Board of Health have just made an official report on the methods and results of the system of sewerage of the Oriental and Manhattan hotels on Coney Island, at the request of the secretary of the Manhattan Beach Improvement Company, in which the following are the principal points: The sewerage of the two hotels is very complete and effectual, extending from the Manhattan eastward more than a mile, and from the Oriental for more than forty-five hundred feet, and the discharge at the eastern terminus of the sewer being fixed at so low a grade below the basements of the hotels that back-water and obstructions in the main sewers are not liable to occur. The mains are so ventilated by special shafts at various points that the hotels and premises are protected against regurgitant gases, while copious supplies of water serve to dilute and adequately force onward the sewage matters. As the sewage gates are raised twice daily at mean ebb tide, the mains are adequately flushed and scoured, and the sewage itself is inevitably swept outward to the sea. In reply to a question whether the hotel sewage as it flows with the ebb seaward may pollute the shores of the mainland of Long Island, and whether it would be destructive to fish or otherwise injurious, or be unpleasant to sight or smell, the committee state that such evils are not probable, and the report concludes as follows: "It would be difficult to devise a more complete and sanitarily safe delivery of the sewage. There can hardly be any cause for criticism or complaint of the system and its practical operation. The

outfall sewer is sufficiently capacious for the daily requirements of a population of many thousands; the entire construction and plan seem to be adequate and thorough, and the work and its results present a model of excellence in a most important kind of sanitary engineering."

—The officers and trustees of St. John's Guild, with a number of invited guests, made a visit of inspection to the new seaside nursery and sanitarium of the guild at Cedar Grove, on Staten Island, on the 28th of July. The trips of the floating hospital are now made regularly three times a week, and each time about twelve hundred mothers and sick children are taken out, at a cost of two hundred and fifty dollars for the excursion.

—Dr. Alouzo G. Chadney, of Spring Street, recently died from the effects of an overdose of chloral, which it is said he took in the dark. The quantity swallowed was about half an ounce.

—The death of a patient in Charity Hospital, an Irish woman, from trichinosis, was reported at the Bureau of Vital Statistics on the 25th of July.

—Small-pox and typhus fever are still somewhat prevalent, though to a much less extent than during the spring. According to the latest accounts there were forty-three typhus fever and forty-eight small-pox patients in the Riverside Hospital on Blackwell's Island.

DISCUSSION.

PSEUDO-SCIENCE AND INSANITY.

MR. EDITOR,—Permit me a few remarks on the very pretentious article entitled *Method in Madness*, which you reproduce from the *Lancet*. I am no psychologist, and have nothing to say on the definition of insanity or on the responsibility of any of the popular murderers of the day. My object is merely to dispute your praise of this article, because it seems to me obscure, founded on vague theories, and contradictory. I cannot admit it as embodying "the best thought" you refer to. So much parade of learning is not needed to show that an insane man may act with method. The article is obscure because there is a confusion, which grows worse as we try to solve it, between a wicked intention and a degenerating brain. The writer says very truly that "the practical difficulty is to avoid, on the one hand, treating the fruits of disease as willful offenses, while on the other we do not allow the supposition or presumption of disease to be employed as an excuse for wrong doing," but the whole tendency of the argument is towards the latter alternative. The "dissolution" or "denuding" theory, on which so much stress is laid, is a very ingenious idea, by which the order of evolution is reversed, the qualities said to be acquired latest going first, but evolution, as applied to man, is so unsatisfactory that it is utterly unscientific to deduce from it a theory from which practical consequences of such moment depend. Evolution has not gained one particle of strength since two years ago Virchow exposed its weakness. Without disputing the correctness of the *clinical* picture that is given of a case of so-called "denuding" disease, we may remark that any definite corresponding pathological sequence

is still to be found, but this is passed over very lightly. The confusion which the writer makes between mind and brain and moral and intellectual faculties is utterly bewildering. Let us pass to some instances.

"A man may lose his faculty of forming a wise judgment long before he is deprived of the power of distinguishing between right and wrong. This is so because it is a higher attainment in moral culture to do right advisedly than simply to perceive the right thing to do." Now we may wonder what connection there is between doing right and forming a wise judgment. The former is a moral, the latter an intellectual, act. They are utterly distinct. Are we to understand that if a merchant of failing mind begins to make foolish speculations, while his knowledge of right and wrong is intact, that business ability has gone before conscience because it is a higher moral faculty? The passage immediately following the preceding one caps the climax of absurdity. "The application of principle to conduct is an advance on the mere recognition of virtue in the concrete, or even the possession of virtue in the abstract." The first clause of this sentence merely states in stilted language the truism that it is easier to preach than to practice, and is intelligible; but what may virtue be that is not applied to conduct? According to this luminous passage a man may get drunk while possessing abstract temperance, and the thief may be one who neglects to "apply to practice" the honesty with which he overflows. This is not caricaturing the passage; it means this if it means anything.

I have endeavored to limit my criticisms to points which the general student may be competent to discuss, avoiding the deeper questions and those demanding special knowledge, but that anything very valuable could rest on so shaky a basis is not to be imagined. My only purpose in writing is to protest against this counterfeit science being palmed off on us as the real thing and the work of the "best minds." T. D.

BOSTON CITY HOSPITAL.

FROM the seventeenth annual report of the Boston City Hospital, which has just been given to the public, we take the following items:—

The whole number of patients in the hospital during the year was 4707, and they were under treatment an average of 21.18 days each, making a total of 99,703 days or 14,243 2-7 weeks.

The number of patients remaining in the hospital April 30, 1880, 289. Admitted during the year—Medical, 2649; surgical, 1685; ophthalmic, 81; total, 4415. Treated during the year, 4707; discharged, 4011; died, 421; total, 4432. Remaining in hospital April 30, 1881, 275; largest number in hospital at any time, 365; smallest number in hospital at any time, 225; daily average number of patients, 273 1-6; average length of stay of each patient, 22 1-5 days. Number of patients treated in the out-patient department, classified according to their diseases:—Medical diseases, 2249; surgical diseases, 1850; diseases of the eye, 1507; diseases of the ear, 303; diseases of the skin, 735; diseases of women, 249; diseases of the nervous system, 274; diseases of the throat, 377; total, 4949.

The entire cost of maintaining the hospital during the year, including every expenditure, excepting the cost of additions and reconstruction of buildings, was at

the rate of \$8.74 1-10 per week, \$125,039.35; but of the patients enumerated above, 403 paid for 1176 1-7 weeks' board \$10,571.83; leaving therefore the sum of \$114,467.52 as the cost to the city of treating 4304 non-paying patients for a total of 13,067 1-7 weeks, which is at a rate of \$8.76 1-20 per week. But after deducting money received from pay patients, stock on hand, etc., and averaging the net cost of maintaining the hospital for the year among all the patients treated, the average cost to the city of board for each patient was \$7.97 5-6 per week.

During the past year the largest number of patients in the hospital at any one time was thirty-seven more than last year; the smallest number at any one time was two more; the daily average was one more, and the average length of stay of each patient was 2 2-10 days less; the net cost of maintaining the hospital has been \$6993.68 more than last year. This increase has been, in a large measure, due to the advance in the cost of nearly all articles of consumption. While the increase in expenditure has been about six per cent., the increase in the number of weeks' board has been a small fraction of one per cent. In other words, the number of patients remaining the same, the expense of maintaining them has been increased. During the year much has been done in renewing and adding to the stock of wards and buildings, in order to complete the furnishing and increase the working stock in the hospital. This expense could not well be deducted, as being a part of the working materials of the house.

It has been apparent to every one familiar with the history of the hospital during the past year that the cases have taxed the resources of the hospital to a much greater extent than usual. The large number of severe injuries and acute medical diseases has at times taxed the working force to its utmost. This is the only hospital in the city admitting contagious and infectious diseases. This fact has brought large numbers of this class, for which, in number and severity, the hospital has never before been called upon to provide. They demanded treatment which was expensive, laborious, and extremely exacting. The demand for treatment of this class far exceeds the accommodations. If the hospital continues to receive contagious diseases to the same extent as during the past year, it must speedily have larger and better accommodations.

The training school for nurses continues to exercise its important part in the running of the hospital, and, during the past year more than previously, has shown its good work in the improved method of caring for the sick. It has rendered the staff aid in utilizing various methods of treatment which could not have been carried out under untrained nurses. The fact of the nurses in the hospital suffering much sickness from their constant attendance on the sick is strongly urged as a reason for the establishment of a home away from the hospital wards, where they could find rest and recuperation when off duty, which would greatly add to their health, happiness, and efficiency, and the trustees believe such a home should be at once established, while the land recently placed in their hands is well adapted as the site for such a building.

The trustees compliment Dr. G. H. M. Rowe, the resident physician and superintendent, as well as the hospital staff, for the great interest manifested by them and the good work they have performed during the year, and they also return thanks to very many friends of the hospital for various donations of useful articles.

THE COST OF HOSPITAL PATIENTS.

MR. CHARLES HAWKINS writes an interesting letter to the *Daily News* on the cost of hospital patients in St. George's Hospital in 1830 and 1880 respectively. The cost is in favor of the year 1880, being less than in 1830 by 1s. 1d. The differences in some of the items are striking. Bread and flour per patient in 1830 cost 10s. 7d.; in 1880, 4s. 1d. Tea and groceries cost in 1830, 5s. 10d.; in 1880, 3s. 4d. Coals and wood in 1830, 10s. 6d.; in 1880, 3s. 10d. Drugs, including leeches, 16s. 5d. and 7s. 11d. in the two years respectively; wine and spirits, 6s. 10d.; and 5s. 11d.; porter and ale, 5s. 3d. and 3s. 1d.; milk, 6s. 2d. and 3s. 3d.; laundry, 2s. 10d. and 4s. 10d.; instruments and surgical appliances, 1s. 9d. and 5s. 2d.; staff £1 0s. 3d. and £1 14s. 3d.; meat, 18s. 4d. and £1 2s. 2d. The difference in the cost of leeches is significant. In 1845 14,800 were used at a cost of £143; in 1880, 425 at a cost of £1 16s. In these estimates the cost of out-patients is disregarded, and the whole expenditure of the hospital debited to in-patients. Mr. Hawkins thinks that not more than £300 or £400 could be subtracted for out-patients, which in 1830 numbered 3000, and in 1880 15,000, many having, he says, very trifling ailments. We fear there is a tendency in hospitals generally to underrate the ailments of out-patients, though they often involve a great deal of suffering. — *Lancet*.

THE NEW YORK LAW TO PREVENT ADULTERATION OF FOOD AND DRUGS.

THE following is the text of the law to prevent adulteration of food and drugs in the State of New York, approved by the Governor, June 2:—

SECTION 1. No person shall, within this State, manufacture, have, offer for sale, or sell any article of food or drugs which is adulterated within the meaning of this Act, and any person violating this provision shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be punished by fine not exceeding fifty dollars for the first offense, and not exceeding one hundred dollars for each subsequent offense.

SECTION 2. The term "food," as used in this Act, shall include every article used for food or drink by man. The term "drug," as used in this Act, shall include all medicines for internal or external use.

SECTION 3. An article shall be deemed to be adulterated within the meaning of this Act:—

[In the case of drugs. (1.) If, when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality, or purity laid down therein. (2.) If, when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia or other standard work on materia medica, it differs materially from the standard of strength, quality, or purity laid down in such work. (3.) If its strength or purity fall below the professed standard under which it is sold.]

[In the case of food or drink. (1.) If any substance or substances has or have been mixed with it so as to reduce or lower or injuriously affect its quality or strength. (2.) If any inferior or cheaper substance or substances have been substituted wholly or in part for the article. (3.) If any valuable constituent of the article has been wholly or in part abstracted. (4.) If it be an imitation of or be sold under the name of another article. (5.) If it consists wholly or in part of a deceased or decomposed, or putrid or rotten, animal or vegetable substance, whether manufactured or not, or in the case of milk, if it is the produce of a diseased animal. (6.) If it be colored, or coated, or polished, or powdered, whereby damage is concealed, or it is made to appear better than it really is, or of greater value. (7.) If it contain any added poisonous ingredient, or any ingredient which may render such article injurious to the health of a person consuming it: Provided, that the State Board of Health may, with the approval of the Governor, from time to time declare certain articles or preparations to be exempt from the provisions of this Act; and provided further, that the provisions of this Act shall not ap-

ply to mixtures or compounds recognized as ordinary articles of food, provided that the same are not injurious to health and that the articles are distinctly labelled as a mixture, stating the components of the mixture.]

SECTION 4. It shall be the duty of the State Board of Health to prepare and publish, from time to time, lists of the articles, mixtures, or compounds declared to be exempt from the provisions of this Act in accordance with the preceding section. The State Board of Health shall also from time to time fix the limits of variability permissible in any article of food, or drug or compound, the standard of which is not established by any national pharmacopœia.

SECTION 5. The State Board of Health shall take cognizance of the interests of the public health as it relates to the sale of food and drugs and the adulteration of the same, and make all necessary investigations and inquiries relating thereto. It shall also have the supervision of the appointment of public analysts and chemists, and upon its recommendation, whenever it shall deem any such officer incompetent, the appointment of any and every such officer shall be revoked and be held to be void and of no effect. Within thirty days after the passage of this Act the State Board of Health shall meet and adopt such measures as may seem necessary to facilitate the enforcement of this Act, and prepare rules and regulations with regard to the proper methods of collecting and examining articles of food or drugs, and for the appointment of the necessary inspectors and analysts; and the State Board of Health shall be authorized to expend, in addition to all sums already appropriated for said Board, an amount not exceeding ten thousand dollars, for the purpose of carrying out the provisions of this Act, and the sum of ten thousand dollars is hereby appropriated out of any money in the treasury not otherwise appropriated, for the purposes in this section provided.

SECTION 6. Every person selling or offering or exposing any article of food or drugs for sale, or delivering any article to purchasers, shall be bound to serve or supply any public analyst or other agent of the State or local board of health appointed under this Act, who shall apply to him for that purpose, and on his tendering the value of the same, with a sample sufficient for the purpose of analysis of any article which is included in this Act, and which is in the possession of the person selling, under a penalty not exceeding fifty dollars for a first offense, and one hundred dollars for a second and subsequent offenses.

SECTION 7. Any violation of the provisions of this Act shall be treated and punished as a misdemeanor; and whoever shall impede, obstruct, hinder, or otherwise prevent any analyst, inspector, or prosecuting officer in the performance of his duty, shall be guilty of a misdemeanor, and shall be liable to indictment and punishment therefor.

SECTION 8. Any Act or parts of Acts inconsistent with the provisions of this Act are hereby repealed.

SECTION 9. All the regulations and declarations of the State Board of Health made under this Act, from time to time, and promulgated, shall be printed in the statutes at large.

SECTION 10. This Act shall take effect at the expiration of ninety days after it shall become a law.

PROGRAMME OF THE INTERNATIONAL MEDICAL CONGRESS OF 1881.

THE following is the revised programme of arrangements for the International Congress at London as issued by the Honorary Secretary-General. The numerous social attractions we omit:—

SECTIONS.

The Sections will meet in the following places from 10 A. M. to 1 P. M. and from 2 P. M. to 3.30 P. M.:—

1. Anatomy — Linnean Society's Council Room, Burlington House.
2. Physiology — Royal Institution, Albemarle Street.
3. Pathology — Chemical Society's Meeting Room, Burlington House.
4. Medicine — The Theater, University of London, Burlington Gardens.
4. Diseases of the Throat (Sub-section) — Astronomical Society's Meeting Room, Burlington House.
5. Surgery — The Library, University of London, Burlington Gardens.
6. Obstetric Medicine and Surgery — South-East Examination Hall, University of London.
7. Diseases of Children — Antiquaries' Society's Meeting Room, Burlington House.

8. Mental Diseases — The Asiatic Society's Meeting Rooms, Albemarle Street.

9. Ophthalmology — Royal Society's Meeting Rooms, Burlington House.

10. Diseases of the Ear — The Assembly Room, Royal Academy of Arts, Burlington House.

11. Diseases of the Skin — Linnean Society's Secretary's Room, Burlington House.

12. Diseases of the Teeth — Linnean Society's Meeting Room, Burlington House.

13. State Medicine — Royal School of Mines, Jermyn Street.

14. Military Surgery and Medicine — The Graduates' Meeting Room, University of London.

15. Materia Medica and Pharmacology — Geological Society's Meeting Room, Burlington House.

Museum — Geological Society's Museum, Burlington House.

DAILY PROGRAMME.

Tuesday, August 2. — 10 A. M. to 6 P. M.: Registration of members and issue of tickets at the office of the Reception Committee in the Royal College of Physicians, Pall-mall East. 8 to 6 P. M.: Reception of the members of the Congress by the Committees at the Royal College of Physicians.

Wednesday, August 3. — 8 A. M. to 6 P. M.: Registration of members and issue of tickets at the Royal College of Physicians. 11 A. M.: First General Meeting, St. James's Great Hall. The chair will be taken by the President of the Royal College of Physicians, Chairman, *ex officio*, of the General Committee, in the presence of H. R. H. the prince of Wales. Presentation of the report of the Executive Committee by the Honorary Secretary-General. The constitution of the Congress and the election of officers will be proposed by the Chairman of the Executive Committee, and seconded by the President of the Congress of 1879. 3 P. M.: Meeting of the Sections. Constitution of the Sections, and other business. 4.30 P. M.: Second General Meeting. Address by Professor Virchow, of Berlin, on 'The Value of Pathological Experiment.' 5 to 6.30 P. M.: Musical Promenade at the Royal Botanic Society's Gardens, Regent's Park. 9.30 P. M.: Conversation at South Kensington Museum (entrance Exhibition Road), given by the English members of the Congress to the foreign members. Every member of the Congress may on this occasion be accompanied by one lady.

Thursday, August 4. — 10 A. M. to 1 P. M.: Sectional Meetings. 1.30 to 3.30 P. M.: Visits to hospitals (Guy's Hospital, London Hospital, St. George's Hospital, St. Mary's Hospital, St. Thomas's Hospital, Westminster Hospital). The medical officers and lecturers will be prepared to receive such members of the Congress as may desire to visit these hospitals and to inspect their schools and museums. 2 to 3.30 P. M.: Additional meeting time for the Sections. 4 to 5.30 P. M.: Third General Meeting, St. James's Great Hall. The address by the late Professor Maurice Raynaud, Paris, *Le Scepticisme en Médecine, au temps passé et au temps présent*, will be read by Dr. Féréol. 6.30 P. M.: Banquet given to a certain number of the members of the Congress by the Lord Mayor of London, at the Mansion House.

Friday, August 5. — 10 A. M. to 1 P. M.: Sectional Meetings. 1.30 to 3.30 P. M.: Visit to Hospitals (Bethlem Hospital, Charing-cross Hospital, King's College Hospital, Middlesex Hospital, St. Bartholomew's Hospital, University College Hospital). The medical officers and lecturers will be prepared to receive such members of the Congress as may desire to visit these hospitals and to inspect their schools and museums. 2 to 3.30 P. M.: Additional meeting time for the Sections. 4 to 5.30 P. M.: Fourth General Meeting, St. James's Great Hall. Address by Dr. Billings, Washington, U. S., on 'Our Medical Literature.' Visit to Messrs. Peart's Works. 8 to 11 P. M.: Conversation at the Guildhall, given to members of the Congress by the Lord Mayor and Corporation of the City of London.

Saturday, August 6. — 10 A. M. to 1 P. M.: Sectional Meetings. 12.15 P. M.: Excursion to Croydon Sewage Farm. 1.45 P. M.: Excursion to Folkestone. 2 P. M.: Excursion to Hampton Court. 4 to 7 P. M.: Reception of a certain number of the members at Kew Gardens, by Sir J. D. Hooker. 4 to 7 P. M.: A Garden Party will be given by Mr. and Mrs. Spencer Wells, at Gledes's Hall, Hampton. 4 to 7 P. M.: A Garden Party will be given by Mr. and Mrs. Saunders, at Fawcett, Wimbledon. 6.30 P. M.: The United Hospitals' Club will entertain a party of the members of the Congress at dinner at the "Star and Garter," Richmond Hill.

Sunday, August 7. — 10 A. M.: A Full Choral Service will be held in Westminster Abbey, sermon by the Very Rev. Dean Stanley, D. D., F. R. S. 3.15 P. M.: A Full Choral Service will be held in St. Paul's Cathedral, sermon by the Rev. Canon Liddell, D. D., D. C. L. 1.30 P. M.: Excursion to Bexhill. Visit to Sir Trevor Lawrence. 2 P. M.: The Royal Botanic

Society's Gardens, and the Gardens of the Zoological Society in the Regent's Park, will be open free to members on this and on every day of the week, on presentation of their tickets. The Royal Gardens at Kew may be visited on Sunday, from 9 A. M. till sunset, and Hampton Court Palace and Gardens from 2 P. M. till sunset.

Monday, August 8. — 10 A. M. to 1 P. M.: Sectional Meetings. 2 to 3.30 P. M.: Additional Meeting time for Sections. 4 to 5.30 P. M.: Fifth General Meeting, St. James's Great Hall. Address by Professor Volkmann, Halle, *Ueber moderne Chirurgie*. Visit to the Docks. 6.30 P. M.: Dinner given to a certain number of the foreign members of the Congress by the Worshipful Master and Wardens of the Society of Apothecaries in their Hall in Blackfriars. 9.30 P. M.: Conversation given by the Royal College of Surgeons to the members of the Congress.

Tuesday, August 9. — 10 A. M. to 1 P. M.: Sectional Meetings. 2 to 3 P. M.: Sixth General Meeting, St. James's Great Hall. Address by Professor Huxley, F. R. S., D. C. L. London, 'The Connection of the Biological Sciences with Medicine.' 3 P. M.: Concluding Meeting of the Congress.

INFORMAL DINNER AT THE CRYSTAL PALACE.

After the concluding meeting, the members, accompanied by their friends, including ladies, will proceed to Victoria Station, for High Level Station (London, Chatham, and Dover Railway), where special trains will be in waiting at four o'clock to convey them to the Crystal Palace. After a visit to the Palace and grounds, an Informal Dinner will take place in the Concert-Room, about seven o'clock. At dusk the fountains will play during a display of fireworks, which may be viewed by members of the Congress from the Queen's Corridor.

BRITISH MEDICAL ASSOCIATION: FORTY-NINTH ANNUAL MEETING.

THE forty-ninth annual meeting of the British Medical Association will be held at Ryde, Isle of Wight, on Tuesday, Wednesday, Thursday, and Friday, August 9, 10, 11, and 12, 1881. President, G. M. Humphry, M. D., F. R. S., Professor of Anatomy in the University of Cambridge. President elect, Benjamin Barrow, F. R. C. S., Consulting Surgeon to the Royal Isle of Wight Infirmary. An Address in Medicine will be delivered by John Syer Bristowe, M. D., F. R. S., F. R. C. P., Senior Physician to St. Thomas's Hospital. An Address on Surgery will be delivered by Jonathan Hutchinson, F. R. C. S., Senior Surgeon to the London Hospital. An Address in Obstetric Medicine will be delivered by John G. Sinclair Coghill, M. D., F. R. C. P. Edin., Visiting Physician to the National Hospital for Consumption, Ventnor. The business of the Association will be transacted in four sections and one subsection, namely: Section A, Medicine; Section B, Surgery; Section C, Obstetric Medicine; Section D, Public Medicine; Subsection, Otolaryngology.

Tuesday, August 9, 1881. — Two P. M. Meeting of Committee of Council. 2.30 P. M. Meeting of the Council of 1880-81. Four P. M. Short service, with sermon by Bishop McDougall. Eight P. M. General meeting in the Town Hall. President's Address; Annual Report of Council and other business.

Wednesday, August 10th. — 9.30 A. M. Meeting of Council of 1880-81. Eleven A. M. Second general meeting in the Town Hall. Address in Medicine. Two to five P. M. Sectional meetings. Nine P. M. Soirée in the Town Hall by the Mayor and the inhabitants of Ryde and neighborhood.

Thursday, August 11th. — Nine A. M. Meeting of the Committee of Council. Ten A. M. Third general meeting in the Town Hall. Reports of Committees. Eleven A. M. Address in Surgery. Two to five P. M. Sectional meetings. 6.30 P. M. Public dinner in the Town Hall.

Friday, August 12th. — Ten A. M. Address in Obstetric Medicine in the Town Hall. Eleven A. M. Sectional Meetings. 1.30 P. M. Concluding general meeting in the Town Hall. Reports of Committees and other business. Four P. M. Garden party in the grounds of the Isle of Wight College, by the President elect and Mrs. Barrow.

The following subjects have been arranged for discussion in the various sections: Section A, Medicine. (1.) Dr. Wade will open a discussion on Dilatation of the Stomach. (2.) Dr. Gowers on Acute Spinal Paralysis. (3.) Dr. Lauder Brunton, F. R. S., on Jaundice. Professor Rosenstein, of Leyden, and Professor Ewald, of Berlin, will take part in the discussions. The following papers have been promised: Barlow, W. H., M. D., Regressive Paralysis in the Infant. Dowse, T. S., M. D., On the Differential Diagnosis of Intracranial Tumor, General Paralysis of the Insane, and Locomotor Ataxy. Drysdale, C., M. D., On Syphilis of the Spinal Cord. Eales, H., Esq., and

Saundby, R., M. D., On the Ophthalmoscopic Appearances of the Fundus Oculi in Chlorosis. Finny, J. Mager, M. D., Notes on a Case of Acute Ascending Spinal Paralysis. Groves, J., M. D., The Treatment of Insanity. Hassall, Arthur Hill, M. D., The Winter Climate of San Remo. Kerr, Norman, M. D., Three Successful Experiments in the Treatment of Dipomania. Skeritt, E. Markham, M. D., A Case of Subcutaneous Emphysema from Spontaneous Rupture of Lung. Tibbits, E. T., M. D., On the Modern Theory of the Action of Digitalis. Tysen, W. J., M. B., Rectal Alimentation.

Section B, Surgery. (1.) A discussion will be opened by Mr. Stokes, of Dublin, on Resection of the Knee in Early Life. (2.) Mr. Edmund Owen will open a discussion on the Early Recognition and Treatment of Spinal Caries. The following papers have been promised. Cross, F. Richardson, M. B., Antiseptic Incision and Drainage in Empyema. Gould, A. Pearce, M. B., M. S., Varicocele. Grattan, Nicholas, Esq., On the Treatment of Spinal Curvature by means of the Cuirass. Greenway, H., Esq., The Value of Suspension in Surgery. Harrison, Reginald, Esq., Treatment of Stricture by Stutching. James, Presser, M. D., Stricture of the Oesophagus. Leardiard, H. A., M. D., On the Treatment of Fracture of the Lower End of the Fibula. Macnamara, C., Esq., Two Cases of Charcot's Joint-Disease. Martin, H., M. D. (Boston, U. S.), A Novel Treatment of Synovitis. McMahon, J. T., Esq., A Case of Psoas Abscess. Norton, A. T., Esq., A new and reliable Operation for the Cure of Web-Fingers. Pyc, Walter, Esq., Spina Bifida. Spanton, W. Dunnett, Esq., A further Series of Cases of Immediate Cure of Inguinal Hernia. Tait, Lawson, Esq., Some Recent Advances in Pelvic Surgery. Teevan, W. F. Esq., Twenty-Five Cases of Lithotripsy at one Sitting. Mr. Coates, President of the Section, in his opening address, will make some observations on the Treatment of Hemorrhoids. Professor Annandale will give a demonstration on Suspension as an Aid in Operative Surgery.

Section C, Obstetric Medicine. (1.) A discussion will be opened by Dr. Malins on the Removal of the Ovaries: *a*, for Dysmenorrhoea; *b*, for Fibroid Tumors. (2.) Dr. Sinclair Coghill will open a discussion on the Mechanical Treatment of Uterine Flexions and Displacements. Dr. Bantock will take part in the discussion. Papers have been promised by Drs. Barnes, Hicks, Murphy, and others.

Section D, Public Medicine. (1.) Mr. Ernest Hart will open a discussion on Vaccination with Calf-Lymph, in which it is expected that Dr. Warlomont, of Brussels, and Dr. Marton, of Boston, will take part. (2.) Dr. Strange will open a discussion on the Origin and Diffusion of Enteric Fever and Diphtheria. (3.) Infectious Diseases, and how to deal with them under the Public Health Act in the best interests of the patients and of the public. (4.) Considerations with regard to Infectious Hospitals: changes in their character, size, site, management, etc. (5.) Cremation. The following papers have been promised: Beveridge, Robert, M. B., On a Peculiar Outbreak of Disease in connection with the Supply of Milk. Davey, A. G., M. D., Prevention of Enteric Fever. Drysdale, C. R., M. D., London Local Death-Rates. Evatt, Surgeon-Major G. J. H., M. D., The New Medical Organization of the Army. Groves, J., M. B., The Isle of Wight as a Health Resort. Hodgson, G. F., Esq., On the Relations of Variola and Vaccina. Palmer, J. Foster, Esq., Cremation. Warlomont, E., M. D. (Brussels), Is it desirable that Vaccination by means of Calf-Lymph should be encouraged in England?

Subsection, Otology. Discussions on the following subjects will take place: (1.) The Relation of Diseases of the Nasal Passages and Naso-Pharynx to Aural Affections. (2.) The Treatment of Acute Suppurative Inflammation of the Middle Ear, with especial reference to Perforation of the Mastoid.

The annual museum of the British Medical Association will be held at the School of Art on August 9th, 10th, 11th, and 12th, and will be open daily from ten A. M. until six P. M.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 23, 1881.

Deaths reported 3566 (no return from St. Louis or New Orleans); 1523 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1082, diarrhoeal diseases 813, consumption 230, diphtheria and croup 121, lung diseases 93, scarlet fever 82, typhoid fever 57, small-pox 42, cerebro-spinal meningitis 26, malarial fevers 24, whooping-cough 23, measles 21, typhus fever nine, erysipelas eight, puerperal fever seven. From *typhoid fever*, Philadelphia 17, New York 10, Pittsburgh and Charleston six, Chicago, District of Columbia, and Buffalo three, Boston, Baltimore, and Cincinnati two, Milwaukee, New Haven, and Nashville one. From *small-pox*, Pittsburgh 12, Philadelphia 10, New York nine, Chicago eight, Brooklyn two, Milwaukee one. From *cerebro-spinal meningitis*, Chicago seven, New York six, Buffalo, Milwaukee, and Fall River two, Philadelphia, Pittsburgh, New Haven, Worcester, Holyoke, Chelsea, and Taunton one. From *malarial fevers*, New York 16, Brooklyn three, Buffalo two, Chicago, District of Columbia, and Holyoke one. From *whooping-cough*, Philadelphia five, Chicago and Buffalo four, Brooklyn three, New York and Baltimore two, Boston, Pittsburgh, and Providence one. From *measles*, New York 10, Chicago and Pittsburgh four, Providence two, Brooklyn one. From *typhus fever*, New York nine. From *erysipelas*, Brooklyn and Chicago two, Philadelphia, Baltimore, Pittsburgh, and New Haven one. From *puerperal fever*, Philadelphia, Chicago, Boston, Milwaukee, Nashville, Lowell, and New Bedford one. Cincinnati reports six deaths from sunstroke and 22 from excessive heat.

Six cases of small-pox were reported in Brooklyn, 26 in Chicago, and 20 in Pittsburgh; diphtheria 29, scarlet fever four, in Boston; scarlet fever 10, diphtheria three, in Milwaukee.

In 39 cities and towns of Massachusetts, with a population of 1,028,717 (population of the State 1,783,086), the total death-rate

for the week was 22.56, against 20.07 and 18.02 for the previous two weeks.

For the week ending July 2d in 149 German cities and towns, with an estimated population of 7,819,277, the death-rate was 26.6. Deaths reported 3999; under five 2182; pulmonary consumption 492, diarrhoeal diseases 283, acute diseases of the respiratory organs 265, diphtheria and croup 127, scarlet fever 65, typhoid fever 49, measles and röteln 41, whooping-cough 34, puerperal fever 13, small-pox (Königsberg two, Münster, Harburg, Aachen two) six, typhus fever (Königsberg four, Posen, Erfurt) six. The death-rates ranged from 9.3 in Wiesbaden to 42.6 in Chemnitz; Königsberg 36.9; Breslau 29.8; Munich 27.8; Dresden 24.1; Berlin 37.2; Leipzig 20.6; Hamburg 22.6; Hanover 18.2; Bremen 15; Cologne 31.6; Frankfurt 22.8; Strasburg 40.8.

For the week ending July 9th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 20.7. Deaths reported 3022; acute diseases of the respiratory organs (London) 195, diarrhoea 180, measles 102, whooping-cough 91, scarlet fever 87, small-pox (London 73) 80, fever 27, diphtheria 12. The death-rates ranged from 11.4 in Portsmouth to 24.3 in Liverpool; Bristol 15.6; Leeds 19.2; Sheffield 19.5; Birmingham 21; London 21.6; Manchester 21.9. In Edinburgh 19.6; Glasgow 22.9; Dublin 20.6.

In the 21 chief towns of Switzerland, for the week ending July 9th, population 479,934, there were 46 deaths from diarrhoeal diseases, acute diseases of the respiratory organs 17, diphtheria and croup eight, typhoid fever eight, measles six, whooping-cough two, scarlet fever one. The death-rates were: Geneva 26.6; Zurich 25.7; Basle 22.6; Berne 22.2.

The meteorological record for the week in Boston was as follows:—

Date.	Barometer.	Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 23, 1881, TO JULY 29, 1881.

HERRARD, VAN BUREN, captain and assistant surgeon. Granted leave of absence for four months. S. O. 169, A. G. O., July 26, 1881.

AINSWORTH, F. C., captain and assistant surgeon. Relieved from duty at Fort Clark and assigned to duty as post surgeon at Fort McIntosh, Texas, relieving Assistant Surgeon Gorgas. S. O. 90, Department of Arizona, July 14, 1881.

TORNEY, GEORGE H., captain and assistant surgeon. The leave of absence granted him from headquarters, Department of the Missouri, June 21, 1881, extended one month. S. O. 76, Military Division of the Missouri, July 25, 1881.

GORDON, W. C., first lieutenant and assistant surgeon. When relieved at Fort McIntosh, Texas, to report to commanding officer, Fort Duncan, Texas, as post surgeon. S. O. 90, C. S., Department of Texas.

Dr. THOMAS WATERMAN has been appointed assistant medical examiner for the Board of Directors of Public Institutions.

The fifth annual meeting of the American Dermatological Association will be held in Newport, R. I., on August 30th and 31st and September 1st.

BOOKS AND PAMPHLETS RECEIVED.—A Medical Formulae based on the United States and British Pharmacopœias. Together with numerous French, German, and Unofficial Preparations. By Lawrence Johnson, M. D. New York: William Wood & Co. 1881.

A Treatise on the Continued Fevers. By James C. Wilson, M. D. With an Introduction by J. M. Da Costa, M. D. New York: William Wood & Co. 1881.

Supplement to Ziemssen's Cyclopædia of the Practice of Medicine. Edited by George L. Peabody, M. D. New York: William Wood & Co. 1881.

A Treatise on Diseases of the Joints. By Richard Barwell, F. R. C. S. Illustrated by numerous Engravings on Wood. Second Edition, revised and much enlarged. New York: William Wood & Co. 1881.

Circulars of Information of the Bureau of Education. No. 6. 1880. A Report on the Teaching of Chemistry and Physics in the United States. By Frank Wigglesworth Clarke, S. B., Professor of Chemistry and Physics in the University of Cincinnati.

SUBINVOLUTION OF THE UTERUS AND NEURASTHENIA.

BY J. S. GREENE, M. D., DORCHESTER.

THE chief purpose of this paper is to invite attention to the importance of neurasthenia as a factor in the production of subinvolution of the uterus, with a view to promoting, on the part of the obstetrician, an increased sense of responsibility for the remoter welfare of certain of his puerperal patients.

I shall present brief notes of a group of cases wherein neurasthenia was manifestly the sole or principal cause of subinvolution, and where, in return, the presence of subinvolution was the sufficient cause of a wearisome persistence or recurrence of neurasthenia. If the fact of this intimate relation between the two conditions be admitted or established the conclusion is obvious that, since each condition is insidious, and often fails to announce its presence by positive symptoms during the puerperal period, each should be watched for with an attentive eye and purpose, to prevent what may well be likened to a malign conjunction of unlucky stars. In entering upon a brief examination of this subject, some remarks of a prefatory nature are needful.

As to the importance of subinvolution as a factor in the production of disease, I believe a fair statement of the present advanced position of authorities upon the subject to be this: that as a general rule it is the cause of areolar hyperplasia, the so-called chronic metritis,¹ and that by itself it is seldom a disease, but to become apparent it needs to be associated with some other pathological condition.² To these statements certain qualifications are necessary. Enlargement of the virgin uterus without the presence of heteroplastic growth is not very rare, and this fact alone is conclusive in favor of the assumption that morbid processes attended by enlargement may arise in the wombs of women who have borne children independently of influences having their origin in the puerperal state. My belief is that subinvolution among pluriparous women is frequent, and increasingly frequent, and is the cause of a very large proportion of the cases of chronic metritis in women who have borne two or more children. I also believe that subinvolution of itself and independently of any attendant or consequent morbid state, such as displacement or catarrh of the endometrium, does harm to the health of the woman. Venous engorgement and stasis naturally attend the condition in question. Increased weight of the passive uterus heavily taxes the supporting tissues. From these conditions arise not only menstrual irregularities, but disordered innervation and blood distribution throughout the body. These most natural inferences are verified by the results of treatment. Cure and correct all the resulting complications, and leave only enlargement, even then aid in the support of the womb at its proper elevation by a perfectly adjusted pessary, and though the patient's condition is immensely alleviated and rendered tolerable she is yet not *cured*. Restoration to something near the normal size and texture of the unimpregnated uterus alone signalizes full recovery of health.

If subinvolution be an evil, *per se*, and if it be in

addition responsible for but a tithe of the ills that follow in the train of chronic metritis, and if it be further, as it is universally admitted to be, a condition very unsatisfactory to treat for cure, if the beginning of treatment be long delayed, then, surely, it takes rank as a subject of prime importance in the department of preventive medicine.

The literature of the subject is especially unsatisfactory in the department of aetiology. One author sees no cases of subinvolution apart from laceration of the cervix; with another inflammation or congestion hold the leading place as causes; while a third has reached the conviction that malnutrition is always at the bottom of the disorder. When faulty innervation or general debility has been somewhat vaguely admitted as a factor, it has been, with barely an exception, as a remote or predisposing condition, local or general, rather than an immediate and all-sufficient influence. I have no controversy to maintain with the advocates of either of these views, but in following my present purpose I pass them by with only one or two remarks.

While malnutrition is often associated with neurasthenia, so that the two conditions are to each other as both cause and effect, I think that the priority of causative influence belongs to neurasthenia. Neurasthenia and subinvolution are often seen together without any evidence of malnutrition, but never are malnutrition and subinvolution combined without very manifest tokens of neurasthenia. If, as is doubtless true, instances of enlarged womb are found associated with laceration or inflammation, it by no means follows that the enlargement is due to the presence of either of these lesions, nor, indeed, that the enlargement is subinvolution at all. In order that cases shall indubitably support the affirmative of such proposition, they must have been observed from the time of confinement, and from the inception of the lesions, and the agency of another possible cause eliminated. The advocates of the theory of laceration will also be asked to prove that subinvolution occurs most frequently after first labors, as lacerations confessedly do. I believe the contrary is susceptible of proof. There is certainly a considerable proportion of cases wherein inflammatory or congestive features appear to predominate. There are others, however, where these features are singularly wanting, and although many cases occupy a middle ground, where traits merge, and become scarcely distinctive, yet it may be convenient for practical uses to admit two types of subinvolution, and to name them respectively the congestive and the neurasthenic varieties.

A characteristic example of the congestive type will most easily be found among those whose circumstances are unfavorable to ease, the laboring poor, or the women, naturally strong, who do their own household work, and are physically overworked. It is characterized by a marked predominance of local over general and reflex symptoms, that is, by pelvic aches and pains, menorrhagia, and leucorrhoea.

The other variety oftener occurs in delicately organized ladies of great nervous susceptibility, who have encountered overstrain from care and anxiety, such influences as especially depress the energies of those possessed of high nervous mobility. The distinctive traits of this variety are the reverse of those named above. Menstrual flow and leucorrhoeal discharge scanty, oftener than profuse; little pelvic pain unless as the result of complications; passive engorge-

¹ Thomas. Diseases of Women, page 285.

² Tilt. Lancet, July, 1876, page 6.

ment rather than active congestion; but a great variety and intensity of reflex nervous disturbance. It is to the examination of this latter type that the remainder of this article is limited.

It is needless to enumerate here the more remote and underlying conditions, so increasingly active and potent in this day and generation, which lead to neurasthenia. They are all comprised in the influences of heredity and those of education. These influences combine to form a being of mobile, susceptible organization, keenly alive to enjoyment and as keenly sensitive to sorrow; one with high capabilities and wakeful activities, and these probably already overwrought, even before marriage comes, with its certain domestic trial of patience and fortitude, its possible bereavements and reverses of fortune. She makes earnest efforts to maintain the accustomed round of social intercourse and domestic responsibility, while the physical functions of matrimony and maternity, either natural or perverted, asserted or unnaturally suppressed, are imperiously demanding and appropriating their moiety of vital force. A nervous system thus overburdened needs but a feather's weight to be overborne. The higher the tension and the more delicate the poise, so much the greater is the strain of the natural power of accommodation of the nerve centres to maintain the just equilibrium of organs and functions. Let now the last feather's weight be applied in the puerperal state, and let this power of accommodation then waver and yield, and the needful nerve influence is wanting which should conduct the process of involution. Unless this failure be recognized and remedied promptly, the womb thenceforward becomes a centre of baneful influence capable of perpetuating weakness and creating innumerable reflex disorders, manifested throughout the system, which may cause every organ and function of the body to become a separate woe. The patient is for a time unconscious of her plight. She rises from childbed and resumes her customary life. The nerve forces may suffice for a period to keep a show of maintaining digestion, nutrition, and muscular power; but the woman is tired, tearful, fearful, and irritable.

Two chances there are for reprieve, and perhaps complete escape, from the doom of chronic invalidism. One lies in the possibility of another, and more fortunately issuing, pregnancy, occurring before inflammation shall have shut the door; the other is held by the physician who, recognizing the dual character of the trouble, shall be able so to deal with its two elements, the local and the general, as to cause each step of improvement on either part to facilitate and confirm a corresponding step on the other, and so lead towards ultimate cure.

The cases I have chosen in illustration of the subject are typical. They all belong to the best class of our countrywomen in respect of mental endowments and strength of character. All have the brunette complexion, with dark eyes and hair, and present the traits usually associated with the nervous temperament. All had had a plurality of children, and were not far from thirty years of age when they came under treatment. All sought professional aid, not for pelvic distresses nor for any suspected uterine ailment, but for persistent debility, symptoms of physical or mental exhaustion, or both, associated with a variety of nervous disturbances, against which combination they had found themselves unable to maintain a struggle. All

were alike wholly free from any trace of laceration of cervix or perinaeum, and from any marked atony or relaxation of the walls of the vagina, bladder, or rectum, a fact important as evidence against the idea that excessive or premature bodily exertion had any direct or mechanical influence on the pelvic organs.

CASE I. Mrs. A., mother of three children, from early girlhood had suffered from a variety of nervous pains. These, in part affecting the stomach, had simulated dyspepsia, and she had never dared to be otherwise than very abstemious in eating. Sometimes she went almost without food for two or three days. Her pregnancies were exceptions to this rule, for then she always ate heartily.

Nothing unusual marked her experience at or immediately after her last confinement, but for many months, both before and after, she shared with her husband the burden of financial anxieties. After unavailing attempts to eat well and nurse the infant, at the end of three weeks from its birth she was carried to her carriage, and drove several miles in search of a wet-nurse. It was not until a year later, and after much watching over serious sickness in the family, and eating less than ever, that a convulsive fit occurred; violent and distressing palpitation of the heart followed, with feelings as of impending suffocation, and her strength suddenly and totally collapsed. Four or five months of extreme nervous exhaustion followed, during which time she was intolerant of noise, of food, incapable of any excitement or effort, obtaining sleep chiefly by the aid of chloral. She then placed herself under my charge. At this time her weight was less than one hundred pounds, its former average being about one hundred and fifteen.

The diagnosis, made complete in due time, was chronic neurasthenia as the primary trouble, with malnutrition (starvation, in fact), present as one result, subinvolution as another. The uterine cavity measured at least nine centimetres.

The first necessity was to inspire the patient with a proper confidence in the powers of her stomach. Having taught her to gratify the cravings of appetite for wholesome, generous food, it was not many weeks before a weight of one hundred and thirty pounds testified to the absence of malnutrition. Restoration of muscular tone and strength followed in due order; but nerve power, steadiness and trustworthiness of nerve function were withheld.

This is the point to take note of, for this is what happens again and again in subinvolution arising from neurasthenia. Either subinvolution reacts, and from being a consequence becomes a cause of neurasthenia; or subinvolution, as a uterine ailment, by virtue of its power to perturb the nerves and simulate other disorders, gives rise to a pseudo-neurasthenia, differing from the real in being not constant, but capricious and variable. Perhaps both forms occur, and combine in different individuals in varying proportions. Certainly a very attentive study of the individual patient is often needed to secure the solution of doubts, and the removal of perplexities having important bearings upon treatment, and one's judgment upon the requirements of a case is liable to frequent need of revision.

What is certain from more than five years' observation of the case of Mrs. A., is this: That after good nutrition and fair muscular strength had been restored, an appearance of chronic neurasthenia continued, varying in degree of severity, however, very nearly in

proportion to the degree of intensity of the uterine engorgement and catarrh. According as the local condition improved under local treatment, the patient's power to do became more continuous, and her perturbations of nerve force became less trying. And further, when all appreciable endometritis had been removed, the engorgement very much lessened, and the uterus comfortably sustained at its natural elevation, by the aid of a high-reaching pessary, there still remained, on the one hand, a liability to depressions and disturbances of nerve influence, — such, for example, as several successive nights of utter sleeplessness, or sudden invasions of general nervous weakness, — and, on the other hand, recurrences or exacerbations of uterine catarrh and engorgement; and the tide of general nerve untrustworthiness was always tolerably synchronous with ebb and flow of local disorder. Only as the basic lesion, the uterine enlargement, at last and radically diminished under a more vigorous and persistent local treatment, has normal, uniform, and continuous capability of energy and tranquillity been possible.

It is several months since Mrs. A. has been released from professional care, and she remains in thoroughly good health. Her uterine cavity now has a depth of sixty-nine millimetres, a measurement which represents a cure of the subinvolution.

CASE II. Mrs. B. had no previous history of neurasthenia, and of uterine disorder only an inconsiderable experience, following a miscarriage which occurred between the two completed pregnancies. When two months advanced in her latest pregnancy, she experienced the shock and grief of a sudden and great bereavement, but maintained throughout the remainder of her term her accustomed cheerfulness and calm. She may have been aided to do this with comparative ease by a certain exaltation of mind associated with her sense of duty towards the unborn child; but the prolonged exercise of will to control or put aside natural emotion doubtless involved a heavy strain upon her nerve power. No unusual experience attended, or immediately followed, her lying in. The usual period of quiet was observed, and all was presumed to be well with her. After a few weeks, however, feelings of mental depression began to grow upon her; and these would alternate with an excited state of feeling impelling her to go. She sought every opportunity for diversion, and got more and more into a state of unrest. A year and a half after confinement she underwent more domestic experiences of a very trying nature, and also suffered some shock from a fall, by the breaking of the cord of a hammock in which she was swinging. Finally she began to show a disposition to faint; and the occurrence of a fainting attack in a theatre was the immediate cause of her placing herself under my professional care, two years after confinement.

The womb was found to be retroverted; and its replacement removed the only pelvic discomforts which she had experienced. It was also deeply congested, tender, and harder than normal to the touch. Its cavity measured ten centimetres in depth, and was filled with very tenacious, transparent mucus, and was easily made to bleed. The vagina was deeply injected and the hemorrhoidal vessels swollen with blood. Accompanying this local condition were symptoms of disordered, one might almost say, collapsed, innervation, affecting almost every important organ and function. The emotions were not always under control of the will; sleep was uncertain; paroxysms of dyspnoea

sometimes occurred. The circulatory system was disturbed; the heart's action weak and frequent. There was total disrelish for food, and constipation. She was unable to apply her mind to reading, or her hands to any employment. Attempts at these, or at walking, were followed by increased prostration. Notwithstanding this extreme state of neurasthenia, there were no visible signs of impaired nutrition. Face and figure remained full, and weight was probably undiminished.

Treatment was begun sixteen months ago. During the last six months the patient has resumed much of her former activity. The only recognizable deviation from the normal state of the uterus is its size, for the subinvolution is not cured. Associated with this, and, as I believe, now chiefly dependent upon it, is a liability to occasional nervous perturbations, and an uncertainty and capriciousness in the display of nerve power, of which power I think she has now regained a moderate reserve supply.

CASE III. Mrs. C. is introduced because it is an example of subinvolution arising solely from neurasthenia of constitutional origin. The lady had always been delicate, and during her first two pregnancies had been greatly restricted in her capacity of effort, but during the whole course of her third and latest pregnancy debility was so profound as to excite anxiety for her safety. All possible means were used for invigoration, including frequent feedings, massage, and the withdrawal of all care, yet she remained a nine months' prisoner to her bed, totally unable to exercise either mental or bodily power. So extreme was the nervous exhaustion that she could not bear the prolonged presence in her room of her dearest friends without harmful effects. Normal labor of two hours' duration took place in September, 1879, terminating in the birth of a healthy female child. The utmost care was used to guide the patient safely through her puerperal convalescence, to reinvigorate her, and at the same time to restrain her from any premature exertion. Trusting to these precautions and to the absence of all suspicious symptoms, no uterine examination was made for nine months after confinement. It was proposed because it was found that with every advantage the patient still remained weaker than was reasonably to be expected, and that she began to experience nervous feelings, which she could scarcely control. The uterus was found inclined towards retroversion, somewhat engorged, patulous, and catarrhal, and with a depth of eight centimetres, indicating a grade of subinvolution, when the patient's natural delicacy of organization is considered, quite sufficient to produce and perpetuate debility and nervousness.

Eighteen months have now elapsed since her confinement, and she has at last regained a near approximation to her earlier standard of strength and efficiency, and is not nervous except for reasonable cause. The uterus is very nearly healthy, and has a depth of seven centimetres.

CASE IV. Mrs. D. is the last which I shall mention. In October, 1876, when her fifth child was three weeks old, she arose from bed, and began a long and devoted attendance upon a member of her family, whose illness resulted fatally four months later. This double strain upon mind and body was attended by menstrual derangements and pelvic sufferings, and was followed by profound prostration of all her energies. The presence of subinvolution was recognized by her physician. Eight weeks of repose was succeeded by

six months of active, congenial, out-of-door life in the parks of Colorado, and she returned home, to appearance, wholly reinvigorated, with pelvic symptoms gone. Soon she began to be annoyed by persistent general pruritus, later, by distressingly severe headaches, and by a sense of returning debility. The uterine cavity measured eight and a half centimetres. The use of the probe caused pain and bleeding. The form and position of the uterus were normal. There was some sensitiveness of the body of the womb and of the left broad ligament, which latter was somewhat thickened. This tenderness was subsequently increased by too violent horseback exercise, and by imprudence in lifting. Local treatment was entered upon in July, 1878, and continued over a period of rather more than a year, with an interruption in the spring, occasioned by a brief absence of the patient in a trip to Europe. About the middle of August, 1879, the menstrual flow came on with unusual and startling copiousness. After this occurrence treatment was discontinued, the womb having regained a sufficiently healthy condition, and a calibre of scarcely more than seven centimetres. Another very abundant catamenial flow occurred in September, and thence dated her sixth pregnancy.

Especial solicitude was felt for the progress of involution after confinement. There was some adhesion of the membranes, and the lochia were not quite normal. Quinine and ergot and hot vaginal lavements were used, the stay in bed was prolonged, and the first effort permitted was carriage exercise. Progress was delayed by an attack of severe abdominal colic, from indigestion, on the thirteenth day after delivery. At the end of five weeks the uterine cavity still measured eighty-one and a half millimetres. At the end of nine weeks the second measurement was made, and indicated the very satisfactory result of sixty-nine millimetres. The patient supplied her infant in part from the breast, and has since remained in good health.

I have reported the foregoing selected cases to emphasize the importance of watching closely all the symptoms in puerperal patients which may be connected with checked involution; of watching these with peculiar solicitude in those patients who may be constitutionally inclined towards neurasthenia, or in those who, not being especially so inclined, have undergone any unusual mental trial or nervous shock; the importance, further, of determining the question by actual measurements, when the *general condition* of the patient presents room for a reasonable doubt, even though the usually accepted local indications, derived from the course of the lochial discharge, etc., be wholly reassuring; the importance, finally, of retaining the full responsibility of *accoucheur* until the vitally important process of involution in each case committed to the physician's charge shall be, in his enlightened judgment, success-fully completed.

A CONTRIBUTION TO THE ETIOLOGY OF CYSTITIS.

C. H. BROCKWAY, M. D., LYNN, MASS.

"To know the natural progress of diseases is to know more than the half of medicine" said Froussac, and few of us would be loth to admit that nothing would advance the science of rational therapeutics more than our increasing knowledge of the natural course of

diseases and their self limitations in many instances. But the very nature of medical practice, as a human art bent quite as much on the alleviation of human suffering as on the cure of disease, has prevented the rapid growth of a knowledge of the natural course which many maladies would take were it not interfered with by the laudable attempt of the physician to relieve painful symptoms and so, in many instances, to modify, for better or worse, the natural progress of the affection.

In this paper I wish to draw attention to one form of cystitis and to its natural history; or rather as much of it as could be learned from a case of long standing occurring in an intimate friend, and offering every facility for close investigation.

M. B. had the following history: From birth until manhood he was in good health; when at twenty years of age he was kicked by a horse, the blow falling on the side of head near one temple. No fracture was found, but he lay insensible for nearly three days. He recovered perfectly except that ever afterward he had frequent and severe headaches accompanied by slight dizziness, and an inability to fix his mind long upon any one subject, yet he was a very active man and carried on a large business. As years passed on his memory became so defective as to seriously annoy himself and others.

When about forty years of age he began to have attacks of sub-acute rheumatism several times a year, but never confining him to bed. He suffered at intervals from spasmodic asthma and accompanying bronchitis; this was a disease of many years' duration. From forty to fifty he was seized from time to time with sudden diarrhoea of a watery character, not connected with any error in diet, but due apparently to nervous exhaustion. When forty-eight years of age he complained of coldness and numbness of the legs from just above the knee to the foot, and walked with a stiff and somewhat staggering gait, especially when he had previously been seated for some time. Locomotor ataxia was feared, but he failed to reveal the proper symptoms, and the trouble with his lower limbs was not progressive. He still considered himself in fair health and pursued his ordinary labors. In this condition, and when fifty years of age, he was seized with a dragging sensation in the region of the bladder and frequent calls to urinate, the water being passed slowly and with difficulty. Soon a thick glairy mucus appeared which adhered firmly to the bottom of the vessel; this continued for several weeks, then mucus mixed with pus was voided, and later, greenish pus in large quantities; no blood was seen at any time. The existence of stone being suspected, Dr. T. B. Curtis kindly explored the bladder several times but discovered nothing. The urethra, which was healthy, allowed a No. 20 (French) bougie to pass freely but would not admit a larger one, owing to the naturally small size of the meatus. The prostatic gland was moderately enlarged but not enough to sensibly occlude the urethra or make it difficult to pass a fair-sized catheter. The urine was acid at all times when examined, and was passed in fair quantity except at one time when the patient had an almost complete suppression of urine for two days. The cause of this anuria was not ascertained and the trouble never reappeared. Roberts¹ says "Disturbance of the innervation of the organs is probably the primary cause and, possibly also in many cases, the direct cause of the suspension of the secretion." The patient drank freely for a

¹ A Treatise on Urinary and Renal Diseases, 2d ed., page 41.

time of an infusion of *tritium repens*, but it had no apparent effect on the cystitis. I then washed out the bladder every other day with warm water followed by the injection of a weak infusion of *buchu*. This was repeated a few times when the discharges suddenly ceased, the symptoms subsided, and the urine became clear and wholly free from mucus. The patient was apparently well so far as his cystitis was concerned. This was about one year from its beginning. The disease ceased as suddenly as it began, and I had reason to believe that the cure was effected by the treatment employed. Three months afterward the disease broke out anew without any known exciting cause; no treatment was instituted for the cystitis this time. It continued with more or less intensity for several months, when it again ceased and never returned.

Its cessation was immediately followed by an intense neuralgia of the brachial plexus. This continued, in spite of treatment, for nearly two years, during which time the patient gradually emaciated and sank into a state of profound nervous prostration; his long-standing bronchitis assumed a purulent character, the bronchial tubes became enlarged and softened, and the lung was rapidly invaded. He soon died of exhaustion, having been confined to his room but three weeks.

Let us inquire into the probable cause of the cystitis detailed above. I think that the existence of stone as a cause can be fairly set aside, considering the peculiar history of the case and the fact that most careful sounding was practiced with a negative result. There was no appreciable disease of the urinary organs, other than the bladder, nor of the neighboring viscera. It was clearly a case of what was formerly called "idiopathic cystitis," which term was hardly more than a cloak for ignorance. During the patient's last attack of bladder trouble I felt convinced that the cystitis was but one link in a long chain of nervous symptoms dating back many years, and that it must have had a centric origin, the disturbance in the central nervous system giving rise to impaired nervous supply and a faulty nutrition of the walls of the bladder, resulting in the subsequent mucous and purulent discharges. A rapid survey of the patient's maladies from early youth will show that they were all apparently of nervous origin. The severe headaches and attacks of dizziness following the blow on the temple, disturbance of memory, muscular (nervous) rheumatism, asthma, sudden watery diarrhoea, numbness and coldness of legs, with staggering gait, non-obstructive suppression of urine (nervous anuria), and intense and long-continuing brachial neuralgia. The fact that the cystitis suddenly ceased when at its height, and was replaced by the neuralgia, is at least suggestive. His ataxic symptoms were not progressive, and at times were hardly noticeable. There was irritability of the neck of the bladder, but no paralysis of the organ or real incontinence of urine. As no autopsy was had I do not pretend to know the exact nature of the centric trouble, but trust that this paper may draw attention to the fact that even purulent cystitis may be but a symptom of some obscure lesion in the central nervous system, and that reputed success by means of local treatment in this disease should be carefully scrutinized with reference to the probable aetiology of the affection.

—The twenty-fifth anniversary of Professor Virchow's appointment as Professor in the University of Berlin is to be celebrated October 13th next.

RECENT PROGRESS IN MEDICAL CHEMISTRY.¹

BY WILLIAM B. HILLS, M. D.

TOXICOLOGY.

Lead. M. Malherbe² has reported a case of chronic lead poisoning from the use of matches containing chromate of lead to light a pipe. The possibility of this mode of poisoning has been previously pointed out, but this is the first recorded case. The lead salt is probably absorbed, for the most part, through the pulmonary mucous membrane; to some slight extent, perhaps, through the skin, owing to the frequent contact of the hands with the matches.

M. Pouchet³ has examined quantitatively the urine of persons suffering from lead poisoning, in order to estimate the effect of potassium iodide on the elimination of lead. During the period of aggravated symptoms the urine contained on an average one milligramme of metallic lead to the litre. Under the influence of potassium iodide, in doses of four to six grammes daily, the elimination of lead increased greatly, but again decreased at the end of from six to ten days, when it became less marked than before the treatment was instituted. But when, after withdrawing the remedy, the patient was allowed to rest for some days prior to the readministration of the iodide, small quantities of lead were again eliminated with the urine. Hence arises the therapeutic indication of employing the iodide for a long time, instituting, however, intervals of repose, during which the remedy is not to be administered. Pouchet also analyzed the urine of patients treated exclusively with potassium bromide without detecting any increase in the amount of lead eliminated. Hence he deduces the inefficiency of the bromide in the treatment of lead poisoning.

Hydrocyanic Acid. Ch. Brame⁴ has detected hydrocyanic acid, *one month* after burial, in the bodies of a cat and rabbit which had been poisoned by the administration of about one gramme of the pure acid.

Morphia. To determine whether, after the administration of morphia, the alkaloid must necessarily be found in the urine, Bornträger⁵ has examined the urine of a number of persons to whom one half to one gramme (grain?) of morphia was given daily subcutaneously. In only rare instances could morphia be detected in the urine.

Landsberg⁶ has investigated the same subject. Having proved that morphia when *mixed* with urine could be recovered, he next turned his attention to cases of poisoning. Animals were poisoned with morphia, administered in some cases by the mouth, in others by subcutaneous injection. The various organs, the blood, urine, and feces were examined for morphia. The latter could be detected in the urine, blood, and organs only after the administration of very large doses. It was detected in the feces whenever the whole quantity administered had not been absorbed.

Bergeron and L'Hôte⁷ call attention to a possible error arising from the employment of the physiological test for morphia in cases where amyl alcohol has been employed to extract the alkaloid, since amyl alcohol, even in very minute quantities, produces true narcotic

symptoms. With reference to this Spica,¹ however, very properly states that the crude amyl alcohol extract should not be employed for the physiological test. The extract should first be treated with acidulated water, and the morphia removed from this and obtained in a pure condition by other solvents.

A. Jorissen² describes a new color reaction for morphia, obtained by the action of concentrated sulphuric acid and ferrous sulphate. A solution of pure morphia is evaporated to dryness, and the residue heated on a water bath with a few drops of concentrated sulphuric acid. A small crystal of ferrous sulphate is then added, the mixture is heated for a moment, and poured into a white porcelain dish containing two or three cubic centimetres of concentrated ammonia solution. The morphia solution sinks by reason of its greater specific gravity, and there is formed at the point of contact of the two liquids a red color, passing into a violet on the borders, while the ammonia assumes a pure blue color. If the two fluids are mixed the blue color only remains. The original article must be consulted for details. The test is recommended as very characteristic and delicate. Jorissen also describes another characteristic test for morphia, in which the morphia is probably first converted to apomorphia by the action of concentrated sulphuric acid at 190–200° F. A dark-green mass is obtained. If this is poured, drop by drop, into a large volume of water, the mixture assumes a bluish color. This is then shaken with ether or chloroform, which assumes first a purple color, finally a very stable blue color. This latter test may be utilized as an exhibit in legal cases.³

Phosphorus. For the detection of phosphorus in cases of poisoning, Selmi⁴ proposes, instead of Mitscherlich's process, to distill the suspended substance with water in a current of carbon dioxide, agitate the aqueous distillate with carbon bisulphide to take up the phosphorus, add a little absolute alcohol to the separated bisulphide, and allow the latter to evaporate. In this way an alcoholic solution of phosphorus is obtained which may be further tested. According to Selmi, if the urine, in cases of phosphorus poisoning, is rendered alkaline with baryta water and precipitated with absolute alcohol, the precipitate gives the reactions of the lower acids of phosphorus with nascent hydrogen. On distilling the alcoholic filtrate, a volatile neutral principle containing phosphorus passes over, also a phosphorus base. The examination of the brain and liver of a person poisoned with phosphorus gave similar results. The brain contained lower acids of phosphorus, whose barium salts were precipitated by alcohol; the alcoholic filtrate contained a volatile body containing phosphorus, also volatile bases containing phosphorus, one of which had an odor resembling that of ammonia and was poisonous. From the liver the lower acids of phosphorus were not obtained, though the other phosphorus compounds were.

Fraenkel and Rohmann⁵ have observed, as did Storch and Bauer⁶ previously, that, in animals poisoned with phosphorus, there is an enormously increased decomposition of the nitrogenous tissues of the body.

The products formed by this decomposition are intermediate products of oxidation between albumen and urea.

URINARY CHEMISTRY.

Urea. Urea by the action of an alkaline solution of sodium hypobromite is resolved into carbon dioxide, water, and nitrogen. This reaction has been proposed for the determination of the amount of urea in urine. Theoretically all the nitrogen of the urea should be evolved. Practically this is not, as a rule, the case; ninety-two to ninety-four per cent. only of the total nitrogen being evolved in the free state. Mehu⁷ proposed mixing either glucose or cane sugar with the urine, before adding the hypobromite, when the whole of the nitrogen would be set free. Subsequently Esbach⁸ and also Jay⁹ stated that a solution of glucose alone evolves some gas under the action of sodium hypobromite. Fauconnier⁹ obtained in the presence of glucose the theoretical amount of nitrogen; but in the presence of cane sugar he obtained only ninety-four per cent. of the total nitrogen.

Professor Wormley¹⁰ states that, according to his experiments, when a solution of cane sugar or of glucose is mixed, in certain proportions at least, with the hypobromite without the presence of urea, the temperature of the mixture increases and its yellow color is discharged gradually, but no gas is evolved. The increase of temperature is more marked and sudden with solutions of grape sugar than with cane sugar. He also observes that the presence of a large excess of glucose entirely prevents the decomposition of urea by the hypobromite. Wormley has made some experiments for the purpose of examining the accuracy of this test for urea without the presence of cane sugar or glucose. The form of apparatus employed was essentially that advised by R. Apjohn¹¹; the hypobromite reagent was made by dissolving one hundred grammes caustic soda in two hundred and fifty c. c. of water and adding twenty-five c. c. bromine to the cooled mixture. In applying the reagent it was diluted with one and one half volumes of water.

A series of experiments was performed, employing one c. c. of a standard solution of pure urea, varying in strength from one to six per cent., variously diluted and added to varying quantities of the reagent. These experiments gave different results; in some only about ninety per cent., or even less, of the nitrogen being evolved, while in others a larger proportion was obtained, and in still others the whole of the nitrogen was set free. It was finally observed that under certain conditions the whole of the nitrogen is uniformly eliminated. These conditions are:—

- (1.) The reagent should be freshly prepared.
- (2.) The urea solution should be wholly added to the reagent, none of the latter being allowed to mix with the urea solution in the containing tube.
- (3.) The amount of urea operated upon should not exceed one part to about twelve hundred parts of the diluted reagent.

Moreover, the diluted urea solution should be added in small portions at a time to the reagent, thoroughly mixed, and the effervescence allowed to cease before

any further addition of urea. When comparatively large amounts of urea are present, it would appear that the surrounding temperature should not be less than about 20°C . (68°F .). In the practical application of the test, if a two per cent. solution of urea is under examination, one c. c. of this solution diluted with five to ten c. c. of water, is placed in the containing tube, and the mixing bottle charged with ten c. c. of the reagent diluted with fifteen c. c. of water; whereas for one c. c. of a four per cent. solution of urea similarly diluted, not less than about fifty c. c. of the diluted reagent should be employed.

During his investigations it was observed, in cases in which the whole nitrogen was not evolved, that so long as the conditions remained the same, the relative proportion of the nitrogen eliminated was pretty uniform. Hence, if the volume of nitrogen evolved from a known quantity of urea under certain conditions, or by a given form of apparatus, be determined, the result may be taken as the basis for the determination of the urea in the urine with sufficient accuracy for clinical purposes.

M. Bretet states, as a result of some experiments lately made by him,¹ that albumen in urines recently passed is not decomposed in the cold by sodium hypobromite; that such decomposition is not appreciable, in decomposing urines, for fifteen days after they are passed, and that it is very slight even after one month, when the increase in the volume of nitrogen evolved is only about two one hundredths. Hence it is not necessary to separate albumen from the urine before determining the urea by means of sodic hypobromite; to do so is often a source of error, for reasons stated in the original communication.

E. Pflüger² states that he has found a possibility of error to the extent of fourteen per cent., in the estimation of urea by Liebig's method, but believes that the method gives good results if Liebig's directions, with certain modifications, are carefully carried out. He then gives directions for making the necessary reagents, and explains his own method of performing the test. The article is however unsuited for abstraction.

Indican. H. N. Heinemann³ has arranged a table which includes three hundred and ninety-six cases investigated by Hoppe-Seyler, Senator, Hemmige, and himself. The following are his conclusions:—

Indican is only exceptionally absent in health. It may vary in quantity in the healthy individual, generally being small in amount, but occasionally as marked as in disease. The most marked increase is obtained in those diseases which affect the alimentary canal, and more especially the small intestines, whether local diseases or general diseases with local lesion. Among these are dyspepsia, gastro-duodenitis, chronic constipation, intussusception, diarrhoea, peritonitis, cholera, lead poisoning, and typhoid fever. In diseases causing inanition, as phthisis, and other prolonged suppurative diseases, as caries and necrosis, a marked increase is found.

Among the diseases producing altered blood-states, some, such as malaria, syphilis, rheumatism, and alcoholism, progressive anæmia, and chlorosis, although always causing the most profound blood-changes, do not always effect a decided increase. This is a singu-

lar exception, to which Senator has called attention, but the investigations are not yet sufficiently numerous to draw conclusions.

Certain nervous disorders, as insanity, epilepsy, Addison's disease, progressive muscular atrophy and paraplegia cause a marked increase. Disordered functions of the kidneys, as in chronic Bright's disease, cause a marked increase. Internal malignant tumors, as carcinomata and sarcomata, cause the most marked and constant increase of all.

*Estimation of Chlorides in Urine.*⁴ In estimating chlorides in the urine, by adding to a measured amount of urine, potassium nitrate, evaporating to dryness and igniting the residue till the organic matter is destroyed as a preliminary step to titrating with nitrate of silver, there is always a loss of chlorine, if the urine contains ammonium salts, on account of the volatility of ammonium chloride. This loss can be avoided by adding sodium carbonate in addition to potassium nitrate. Feder and Voit,⁵ in order to avoid all loss, employ for each ten c. c. of urine three grammes sodic carbonate, and two grammes potassium nitrate.

Habel and Fernholz⁶ recommend the following process: To the urine add one half its volume of baryta mixture and filter; measure off fifteen c. c. of the filtrate, make it acid, after neutralization, with ten drops dilute nitric acid (Sp. Gr. = 1.119), and add the ordinary standard solution of silver nitrate as long as a precipitate of silver chloride is formed. This process is rather tedious and inconvenient, since it is necessary to filter and test the filtrate with the silver solution and with a solution of sodium chloride in order to determine when the silver nitrate ceases to produce a precipitate. The results obtained agree closely, however, with those obtained by titration after ignition with sodium carbonate and potassium nitrate.

Salkowski⁷ has for some time employed Volhard's method for estimating the chlorides and considers it the most satisfactory of all the methods. He performs it in the following manner: Ten c. c. of urine are diluted to sixty c. c., acidulated with two c. c. pure nitric acid, (Sp. Gr. = 1.2) and decomposed with fifteen c. c. of the silver solution usually employed for the estimation of chlorides. The mixture is vigorously shaken until the fluid is clear, diluted with distilled water to one hundred c. c. and filtered through a dry filter paper. To eighty c. c. of this filtrate, five c. c. of a cold saturated solution of ammonio-ferric alum are added, and the silver determined by titration with the standard solution of ammonium sulphocyanide. The calculation is simple. Salkowski considers the method by titration after ignition with sodium carbonate and potassium nitrate especially inaccurate, since Steinauer has recently shown that part of the chlorine excreted in the urine is in combination with organic substances.

C. Arnold⁸ also recommends Volhard's method, although the working details of the process, as performed by him, differ somewhat from those employed by Salkowski.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

TWO CASES OF CYSTITIS IN THE FEMALE, UNDER THE CARE OF DR. J. COLLINS WARREN.

REPORTED BY C. P. STRONG.

CYSTOTOMY FOR CYSTITIS.

CASE I. May 9, 1878. K. C., aged forty-three, married, no children. Patient states that following a severe cold ten years ago she first noticed some pain when passing water, but this was not severe. Shortly afterwards she was married, and within a year micturition grew very painful as well as frequent. When the urine was retained any length of time the pain became intense, if voided at once she suffered from burning, throbbing sensations in the urethra and bladder. She had undergone thorough treatment by vesical douches, dilatation, and cauterization of the urethra, and internal medication, not only without relief, but her condition had grown steadily worse.

The urine was full of pus, blood, and bladder epithelium.

The patient was sent to Dr. Warren by Dr. W. Symington Brown, of Stoneham, that cystotomy might be done as a last resort. This was performed by making an incision of little more than an inch in length through the vaginal wall upon a probe passed into the bladder, and stitching the edges of the vesical and vaginal mucous membranes together with an uninterrupted suture of carbolized catgut. Two days after the operation the urine flowed almost continuously through the fistula, and she was much relieved from the pain in the bladder. In one week she was entirely free from pain. After being taught to wash the bladder per urethram once daily with warm water, she was discharged with instructions to report from time to time for examination of urine.

October, 1878. The patient reporting at the hospital stated that until recently she had been entirely relieved from her former symptoms, but that now a small amount of urine remained in the bladder, and caused her severe pain. As on examination the opening was found contracted, so that it admitted only the tip of the little finger, it was enlarged at each end along the median line of the vagina, and, as before, the vesical and vaginal mucous membranes united by uninterrupted carbolized catgut sutures, leaving a fistula about two and a half inches long. Following this operation there was a slight secondary hemorrhage; with this exception convalescence was uninterrupted, and the patient was discharged in two weeks entirely relieved.

July, 1880. The urine having been normal for some time, and the patient being in good condition, the operation for closing the opening was performed. The edges of the fistula, which had contracted very little, were refreshed and brought together by seventeen silver sutures; these did not include the vesical mucous membrane. A soft rubber catheter was fastened in the bladder. Up to the fifth day of convalescence there had been no leakage into the vagina, then, for several days, the patient had severe diarrhoea with tenesmus, which probably interfered with union, as immediately after the urine escaped in considerable quantities through the fistula. When the stitches were re-

moved on the tenth day a small part of the wound was not united. The patient was sent into the country to build up her strength, and September 23d she reported for operation again. This was performed in the same manner as before, seven stitches being required. Nothing retarded convalescence, and on removal of the stitches the opening was found firmly closed. For several days there was urgent desire to pass water very frequently, and severe pain if the urine were retained, so that it was feared the operation had been premature, but as the intervals between the acts grew longer until they extended over several hours, the pain was attributed to dilatation of the bladder, which had become contracted from disuse.

The patient reported at the hospital nearly five months after the last operation. She stated that she was entirely free from any pain or discomfort in the bladder, and that she could retain her urine the normal length of time.

From its influence on her general condition it is worth noting that the patient reduced her weight sixty-five pounds by "banting" during one year, having previously grown very stout under a largely milk diet.

CYSTITIS WITH GRANULATIONS AND FORMATION OF CALCULI.

CASE II. L. M., thirty-eight. The patient stated that for more than four years she had suffered from frequent and painful micturition, so that she had been a constant invalid. During this time she had been subjected to various constitutional and local medication without any benefit. Very severe hemorrhages had followed vesical douches. At times she had noticed small calculi passing out in the urine. The urine contained blood, pus, and crystals of triple phosphate. She was examined for stone without ether; none was found, but there was very great tenderness noticed all over the mucous membrane of the bladder. Under ether the urethra was rapidly dilated, the finger introduced and swept around the bladder. The mucous membrane was studded with fungous granulations, each having on its crest a concretion of phosphates. This condition was much worse in the immediate vicinity of the neck. The granulations were destroyed by the finger-nail with very little bleeding. The next day the patient was more comfortable than for some time before the operation. There was an appreciably longer interval between the acts of micturition, and no incontinence. The bladder was washed out daily with a saturated solution of boracic acid, and the urine kept well diluted. The patient's condition steadily improved, so that at the expiration of three weeks there was no trace of blood or pus in the urine, and it could be retained as long as in health. Being instructed to wash out the bladder herself for a month longer, and to return should any of the former symptoms recur, she was discharged. A letter received about six weeks after the operation stated that she was entirely free from any bladder trouble. Since then there has been no report, so that probably there has been no relapse.

—Madame Paul Broca, the widow of the distinguished anthropologist, has expressed her intention of founding a prize of the value of fifteen hundred francs, to be awarded every two years for the best essay on some subject in human anatomy, comparative anatomy or physiology.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. BLAKE.

REPORTED BY DR. JOHNSON, HOUSE OFFICER.

VESICAL CALCULUS IN A WOMAN; DILATATION OF THE URETHRA AND REMOVAL OF THE STONE BY FORCEPS.

CASE I. B. H., single, aged eighteen, entered the hospital March 28th with the following history. Sick three weeks; complains of pain, referred to region of bladder; painful micturition and sudden stopping of the stream; has not menstruated for four months. On examination the uterus was found enlarged, occupying the median portion of the lower part of the abdomen, and reaching to about three fingers' breadth above the symphysis pubis; cervix soft and of a velvety feel; vagina moist and soft; no other symptoms of pregnancy were found except a slight darkening of the areolæ of the breasts, and occasional morning sickness.

Urine pale; alkaline, specific gravity 1019; albumen, one eighth per cent.; sediment-crystals of triple phosphate, blood, pus, round and pavement bladder epithelium, and much mucus. The day after entering there was retention of urine and on passing a catheter a stone was discovered. On the following morning, under ether, the urethra was dilated with cervical dilators and the index finger. Stone forceps were introduced and a mixed calculus withdrawn. The shell of the calculus was phosphates and the centre calcic oxalate. It weighed one hundred and fifty-three grains. On the morning after the operation, April 1st, patient had control over the bladder.

April 2d. Severe pain in back and right hip; persistent vomiting; tongue dry and covered with brown coating; the pain is intermittent and so severe that patient screams out. Chloral was given by the rectum, but the vomiting was only partially relieved. On examination no contractions of the uterus could be felt, and the external os was not at all opened. Patient was then fed for a day and a half by the rectum.

April 4th. No vomiting for eighteen hours. Gin punch was given by the mouth and retained without causing nausea.

Patient gradually but slowly improved from this time. Each morning at five fifteen grains of chloral were given per rectum, and there was no return of the nausea and vomiting.

April 20th. Patient discharged.

She had perfect control over bladder, except when crying or coughing, at these times there was a slight dribbling of urine.

Nothing was detected in the bladder by the sound, and an examination of the urine showed it to be normal.

ANEURISM OF THE ARCH OF THE AORTA.

CASE II. G. R., aged twenty-four years, laborer, entered the hospital March 12th. Has had a cough for eighteen months. For the past six months has had pain in chest, referred to a point just beneath the middle portion of the sternum, but the pain has not been severe enough to deprive him of his sleep, or to cause any inconvenience; hoarseness of several months' duration; one week ago first noticed a tumor situated about the first piece of the sternum; at the same time was troubled with difficult deglutition; tumor when first noticed was as large as an orange; just previous to no-

ticing it had severe pain in upper part of chest just where the tumor appeared; the pain has continued severe. On entering, a swelling, irregular in shape, the size of a cocoa-nut, extended from just below the thyroid cartilage sixteen centimetres in median line; on the left side to third intercostal space; on the right side to third rib; transversely the tumor measured sixteen centimetres; diagonally in a line from left side of neck towards right nipple seventeen centimetres; in a line from right side of neck towards left nipple twenty centimetres; in highest point, five to six centimetres above the level of the chest; tumor was tense, somewhat elastic, and pulsation could be felt in all parts of it; veins of neck engorged and tortuous; breathing not interfered with; no thrill or murmur detected; no difference in pulsations of radial arteries; same was true of the carotids and femorals; swelling and pain over jugular veins of right side of neck; prominence of eyes; no œdema; tongue moist with its papillæ much enlarged; bowels constipated; no trouble with micturition; appetite good; temperature 99.8° F.; pulse 82; no history of syphilis; patient was kept perfectly quiet and in as nearly the horizontal position as possible.

Diet to consist of food rich in fibrine, and the daily quantity to be small. R. Vini antimonii, gtt. xx., tr. aconitii rad., gtt. i., tr. digitalis, gtt. x. M. Take every three hours.

March 15th. Size of tumor much increased during the past twenty-four hours; tissue over tumor on the left side œdematous and quite red.

March 18th. Severe pain in head; pain in tumor worse at night; increased difficulty in deglutition; eyes more prominent; unable to lift left hand to head; grasp of the left hand weaker than that of the right; pain in left upper arm.

March 21st. Left arm, from shoulder to wrist, œdematous.

March 23d. Difficulty in deglutition and breathing much increased; pain in tumor more severe; coughs more than at any previous time since entering hospital; complains of dizziness.

March 27th. Deglutition and breathing difficult; at times orthopnoea; increase of cough; voice almost gone.

March 28th. Breathing very labored; tracheal râles; severe pain in tumor; sulphate of morphia, one eighth grain *sub cute* given.

At eleven p. m. patient died, apparently of suffocation.

During the attacks of dyspnœa Hoffman's anodyne was used and invariably gave relief.

Autopsy. Left lung completely adherent; one hundred and fifty centigrammes clear serum in the pericardium; heart in normal position; diaphragm at fifth interspace on the right; diaphragm at fifth rib on the left; right lung free; liver enlarged, reaching two fingers' breadth above umbilicus; there was an aneurism of the arch of the aorta; the innominate and branches seemed to be perfect; the left carotid was not involved, while the left subclavian could not be traced; spleen not abnormal; kidneys injected; capsules removed readily; lobules healthy; stomach not abnormal; some scrofulous ulcers in lower part of ileum; sac of aneurism composed of degenerated muscle and fibrous tissue, wall of aneurism having disappeared; chronic endarteritis of aorta extending to bifurcation; subperitoneal hemorrhages in pelvis over bladder, and in region of sacrum between the internal iliaes.

INTERMITTENT APHASIA (EPILEPTIFORM ATTACKS), DISEASE OF ARTERIOLES.

BY S. G. WEBER, M. D.

Mr. D., aged fifty-four, sailmaker, was seen first February 21, 1873. The following history was given: He had had yellow fever many years previously, otherwise no severe sickness; he had for many years had periodical headaches, recurring once a month or so, sometimes very severe; the pain was frontal attended with a sensation of a band around his head, not accompanied with nausea; he had always devoted himself carefully and closely to business; did not worry about business at home, and always slept well.

In May, 1872, he had his first attack of disturbance in speech, these attacks had recurred afterwards every month or so at first, later every two weeks, or even once a week. First there was headache, then he was dizzy, then could speak only a little and that not connectedly, and had also loss of memory for some things. The headache might exist a few days previously to the loss of speech. At times there was also loss of eyesight and loss of hearing, but generally no such trouble. There was usually no change in the expression of his face and no change in motor power; during the loss of speech he had been able to leave his place of business and return home in the horse-car, walking to and from the car. If he did not try to talk there would be nothing to indicate any disturbance. He was rather irritable during the attack, apparently from impatience at not being able to talk, at least this was the opinion of his friends. Between the attacks he did not remember what happened during the attack; he also sometimes used wrong words and dropped words, talking as if intoxicated.

When seen he had nearly recovered from an attack, he talked in a restrained manner; his memory seemed to be poor; he was irritable; his pupils were about one sixteenth of an inch in diameter, and did not dilate when the light was diminished; the eyes moved naturally, and there seemed to be no impairment of vision; his tongue was protruded straight; the motion of both hands was the same, but they were a little unsteady; he walked naturally and well even with the eyes shut; he stood on the right foot rather more easily than on the left with the eyes shut, but the difference was very slight.

Sensation was a little more acute on the right than the left in hands and legs, he recognizing two points on the right hand at one eighth inch distance, on the left at one half inch; on the right leg at seven eighths inch, the left leg one and one fourth inches; on the face he often said there were two points when only one was applied; hearing was slightly better with the left ear, but not good in either; there was no tenderness over the spine nor over the sympathetic ganglia in the neck; his head was feeling badly from a sense of pressure across his forehead.

He was not seen again for nearly two weeks, during which time there had been no new attack; then he seemed better, but still he lost a word occasionally in talking; his memory was better. A little more than two weeks later he had a slight attack and in a week more a severe one. Between these two he had not been quite so well; he had been somewhat excited, especially in regard to business matters, had slept poorly, but the day before the severer attack was quiet and calm. In the morning he went to his business, but about 2.45

p. m. returned home unable to talk, could only say "yes" and "no;" saliva ran from his mouth, his face was pale; he had a dose of bromide of potassium and went to sleep. He was seen at six p. m., was quiet; his face rather flushed; could not talk connectedly; was especially troubled with using nouns; at times he used the wrong words; did not seem provoked nor angry at it, even smiled at his mistakes; when the right word was mentioned he recognized it and seemed pleased; pulse 90 to 96; temperature under left axilla 100° F., under right 101° F.; a pencil and paper were given him but he could not write. The next morning he talked well, with a pulse of 72; then was first noticed a slight loss of tone in the muscles on the right side of the face; he could then stand on the left foot with his eyes shut better than on the right.

There were certain mental symptoms which were not fully noted, most marked during the above attacks, such that it seemed best he should be restrained; he was very willful and obstinate; would not listen to advice as to giving up business or changing his habits. As he was incompetent to manage his business with safety, and it was difficult for his family to manage him, I advised his being sent to an asylum. This was objected to and I saw nothing more of him. He was, however, subsequently sent to an asylum, and in January, 1874, he died. I made the autopsy with Dr. Fisher's assistance January 19th. I do not know how long he had been dead.

The brain was the only organ seriously diseased, the abdominal and thoracic viscera being healthy.

The skull was thin; the dura mater not strongly adherent to it; there was no unusual opacity of the membranes; no excess of serum; the brain substance was softer than it is often found, perhaps post-mortem softening; the left isle of Reil and the sphenoidal lobe were very soft; the corresponding parts on the right were less soft; there was a slight shrinking or atrophy of the cortical layers; the larger arteries were healthy; in several places the pia mater was adherent, tearing off with itself thin layers of the gray substance; on making sections the smaller arteries projected above the section stiff and bristle like,—they had undergone calcareous degeneration, their walls being thickened; and yielding before the knife they were pressed into the brain and when divided sprang up again, so projecting above the surface of the section.

The brain cells in the softened parts were darkly pigmented and contained fat globules. The smaller vessels were surrounded with pigment and granular corpuscles, their walls were thickened and there was a calcareous deposit, forming very nearly a continuous sheath for the vessels; this degeneration affected the smaller vessels very generally.

This case is rather unusual in two or three respects. It is rare to have aphasia without motor disturbance in the limbs. Mr. D. had several times attacks of aphasia, in one of which I saw him, with no loss of power, so far as could be recognized, and apparently no other disturbance of function. As there was also loss of power to write, agraphia, from the inability to conceive the words, and transmit the verbal ideas to the hands, not from inability to hold pen or move fingers, it is impossible to know how much disturbance of mental function there really was. Yet there must have been at least a limited power for mental action; thus he was attacked suddenly in a friend's counting-room with inability to talk; he knew enough to rec-

ognize the attack, to take his hat and go to his own shop, then to walk to the cars, to take the right car out of a large number passing the Tremont House, to pay his fare, to get out at the right street, and go to his own house. All this was possibly somewhat automatic, yet there must have been considerable cerebral control to carry out such a long-continued course of automatic action.

I remember one other case of somewhat similar nature, but limited to a single attack. This was in a patient who had suffered from nervous symptoms several years, and had been under observation more than a year. He had had numbness in his legs, attacks of uncertainty of memory, then, after some months, lost the use of his left leg and arm, which was recovered after about twenty-four hours; about two weeks later had a similar though shorter and less severe attack. There was then an attack of loss of memory which lasted two days without additional loss of power, accompanied with febrile reaction. Possibly this attack was really aphasic in character like a subsequent attack. It was soon after the above attack of loss of memory that numbness was noticed in the little toe of the right foot. Some time later, while lying on a lounge, he found he could not speak; being quite frightened and agitated, he immediately rose, went to his brother's house, and the two together took a carriage, and came to see me. When I saw him he was able to talk. There was complete aphasia with no motor paralysis. I subsequently learned of his death with symptoms of cerebral hæmorrhage. There was no autopsy.

Another peculiarity was the intermittent character of the aphasic attacks. It is not necessary to dwell long on this point, as this has been made sufficiently evident in the account of the case. When I saw him, at least twice, there was still impairment of speech, once words being misplaced, another time nouns having dropped out of his vocabulary, but these occasions were immediately after an attack, and at other times, especially earlier in the disease, there was much more complete recovery, so that a casual observer would notice little or nothing wrong.

The mental condition was not normal, however, between the attacks, as shown by the change of disposition, by irritability, by unreasonable opposition to proper precautions for his own safety, and for the safety of his business relations, so that finally an asylum was the only resort.

Dr. Ball¹ reports cases of temporary aphasia which he ascribes to spasm of cerebral arteries, giving rise to local cerebral anæmia. The present case is easily explained by a local cerebral anæmia, due to the instability of the circulation through the diseased vessels, the current of blood being checked by comparatively slight causes.

The pathological lesion was peculiar. At the autopsy there was a limited amount of softening of the isle of Reil and the sphenoidal lobe on the left and to a less extent on the right. It must be taken into account that the body had been removed from the asylum to his home, and this softening was in part post mortem. It must also be remembered that several months had elapsed, at least nine, between the time that he was last seen and his death. The softening was altogether too slight to have existed so long previously, and must be referred to the later changes,

preceding death by a comparatively short interval. The aphasia was then not caused by a gross lesion of the brain substance, and must be referred to the disturbance of circulation caused by the disease of the small blood-vessels.

The changes in the blood-vessels were entirely different from anything I have elsewhere seen. It is not unusual to have small patches of calcareous degeneration in the coats of the arteries, and even crystals of calcareous matter may be deposited on the adventitia of the vessels, but in this case the middle coat of the smaller arteries was entirely transformed into a calcareous sheath encircling the vessel; this change was also very general. It will be easily understood how such a change, even if limited in extent, would interfere with the contraction and expansion of the vessels, and so seriously impair the normal action of the brain. Unfortunately it was not noted whether the portions found most softened at the autopsy showed this arterial change in any greater degree than other portions. My recollections are that they did not. The other changes in the brain have no special significance so far as concerns the aphasia. The slight atrophy of the cortex may have been due to age. The adhesions of the pia mater would explain the other mental phenomena.

The fact that between his attacks he remembered little or nothing of what happened during the attack, the recurrence of the attacks at periods more or less regular, their increasing frequency, the fact that they succeeded or were added to periodical headaches might lead one to consider the attacks of aphasia as an unusual form of epilepsy. It is interesting in this connection to recall that Living mentions that periodical sick headaches or megrim frequently change at a later period of life into epilepsy. Mr. D. had had for many years periodical headaches, recurring once a month or so, sometimes with great severity. At first the aphasic attacks recurred once a month, beginning with a headache. It is also of interest to mention that when first seen bromide was employed, and he had an interval of more than a month before the next attack.

Dr. H. Jackson² reports a case of epilepsy which was preceded and followed by aphasia, but the attack was attended during loss of consciousness with convulsions of the right side.

Oedman³ reports a case of loss of voice following epileptic attacks, which were the result of a blow upon the head. Here, too, there was spasmodic action, the right arm being chiefly affected.

Taking into consideration the mental symptoms, the course of the disease, and the cortical lesions found after death, we might be justified in regarding the affection, taken as a whole, as general paralysis, varying somewhat from the usual course of such cases in consequence of peculiarities of the lesion. When seen by me, however, the aphasic and epileptiform character of the symptoms were much the most noteworthy.

— According to London dispatches to the daily press, the decision of the International Medical Congress not to admit female doctors to the meeting has caused much dissatisfaction to the forty-three applicants affected by it. They have entered a protest against their exclusion from the meetings. The Queen is reported, we know not how truly, to regard the female practitioner with especial disfavor.

A CASE OF BILATERAL LACERATION OF THE UTERINE CERVIX, OF FIVE YEARS' DURATION, COMPLICATED WITH PROCIDENTIA; OPERATION; RECOVERY.¹

BY GEORGE H. RIXBY, M. D., BOSTON.

MRS. D., aged thirty-six, multipara, a tall, stout brunette, consulted me in April, 1880, for an affection which had occasioned her great suffering for a number of years.

Five years previously she gave birth to an unusually large male child. The labor was lingering, and finally terminated instrumentally. There was an unusual amount of hemorrhage. Convalescence was slow and tedious, much more so than on any previous occasion. Immediately after leaving the bed there was a marked tendency to prolapsus of the uterus. This continued to increase until at a period seven months from her confinement, at each act of defecation the organ was forced entirely without the vulva. The displaced organ was easily reduced by the patient herself, and held in position by means of a large sponge. Later the tendency to prolapsus was such that the method for relief, so satisfactorily employed before, ceased to be effectual. After a period of fifteen months' lactation the menses returned, lasted eight days, and always profuse. This circumstance, together with the effects of the other troubles, debilitated her exceedingly, and finally compelled her to seek medical aid.

Inspection showed the large, peculiarly formed organ in a complete state of procidentia, the cervix lacerated bilaterally, each lip measuring two and a half inches in length. The organ was in a condition of subinvolution, the cavity measuring four and one half inches.

Convinced of the absence of all complications, such as the result of pelvic inflammation, the organ being freely movable in every direction, in May, 1880, without any preliminary treatment, four days after the cessation of catamenia, with the valuable assistance of my friends, Drs. F. E. Bundy and John G. Blake, of Boston, the usual operation was performed. Five silver sutures on each side were sufficient to restore the cervix to its normal size and form.

The after-treatment consisted as follows: after the third day carbolized injections twice a day, drawing the urine for six days, confinement of the bowels for a week, with unstimulating diet for the same length of time.

The sutures were removed on the eighth day, union having taken place by first intention. In order to favor involution it was deemed advisable to keep the patient in the horizontal position for five weeks. On the fourth week already it was ascertained that the tendency to displacement, either when standing or at stool, had greatly diminished. Three months after the operation she was discharged, cured. Six months later she was reported entirely well, attending to all her domestic duties without mechanical support, with menstruation normal.

— The subject of cremation is under the consideration of the Japanese Government, who have appointed a special commissioner (Mr. Monosuke Sano) to study the subject. He is now investigating the merits of the Italian system at Milan.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. H. RICHARDSON, M. D., SECRETARY.

LEAD-POISONING.

APRIL 4, 1881. DR. J. J. PUTNAM spoke of a case illustrating the danger of overlooking lead poisoning as a factor in nerve disease. The only symptoms were numbness and slight weakness of the hands, with some atrophy of the balls of the thumbs. There was a very slight discoloration of one gum. Dr. Wood found lead in the urine.

DR. C. H. WILLIAMS asked whether in undoubted cases of lead disease it was not often necessary to give iodide of potash before the presence of lead could be detected in the urine.

DR. WOOD answered in the affirmative.

DR. PUTNAM asked whether iodide of lead is eliminated by the saliva, and whether, therefore, it is wise to use laxatives in connection with iodide of potash.

DR. WOOD could only say that in some cases when the blue line is absent from the gums the administration of iodide of potash will cause it to appear without any additional exposure to lead.

DR. J. S. GREENE then read a paper upon

SUBINVOLUTION OF THE UTERUS AND NEURASTHENIA.

DR. WEBBER mentioned a case in which he was called on account of extreme nervousness. The very annoying nervous symptoms seemed to him dependent upon an enlarged state of the uterus, and he consequently referred the case to Dr. Sinclair. The woman rapidly improved under treatment directed to the local condition.

DR. REYNOLDS spoke of the extreme rapidity with which involution takes place in ordinary cases. He thought the important question to answer was as to whether the improvement in neurasthenic symptoms kept pace with the retraction of the uterus.

DR. CHADWICK expressed doubts as to the interdependence of the local and general condition. His impression was rather that there was one general cause for both conditions rather than that one depended on the other. In some cases of uterine disturbance, especially of displacement, he has seen an accompanying train of nervous symptoms greatly improved after local treatment. He thinks that in many of these cases excess in coition is a pregnant source of trouble, and that its interruption in the course of treatment is an important factor of success. He has not had much success in the treatment of subinvolution by local measures.

DR. WEIR MITCHELL expressed his interest in the paper and subject. He said that he had not had occasion to refer cases of neurasthenia, or "nervous exhaustibility," as he preferred to call it, to subinvolution, possibly because not having much experience in uterine ailments he did not look to that organ for an explanation of symptoms as a specialist might. He was glad to have his attention called to the subject, that he might inquire into it in future cases. He said that he was inclined to compare the relation of the uterus to the general nervous system to that existing between the eyes and brain. A pair of defective eyes may cause no irritation to a healthy brain, but when the

brain is affected by any disease these eyes may become a fruitful source of discomfort. Just so the uterus, affected by some slight ailment which is ignored or well borne by a healthy nervous system, may cause much trouble when the nervous system is exhausted, and may greatly aggravate the nervous disorder.

COW-POX.

DR. HENRY A. MARTIN gave an interesting oral report of his investigations into the cases of supposed cow-pox reported briefly by Dr. Cushing at the meeting of February 1st. Contrary to his expectation, he found them to be cases of genuine vaccinia, as he tested by inoculation upon children and upon heifers. Many years ago Dr. Martin offered a considerable reward for any cases of genuine cow-pox which investigation should prove to be authentic and to have their origin in none of the stables where vaccinia is cultivated. He investigated more than thirty supposed cases, and found various pustular eruptions, but in none of them true vaccinia. In 1872, through Dr. Tarbell, he heard of a pustular eruption among some cows at Hingham. When he saw these cattle, however, the disease had already run its course, and although the scars left were very suggestive of cow-pox, still there were no means of verifying their character. It is interesting that the present cases should be found in the same sections of the country, which renders it probable that Dr. Tarbell's cases were indeed true vaccinia. This view was further confirmed by the statement of various hands about the dairies in Cohasset, who said that for years such cases had been not infrequent, and several of the milkers had had pustular eruptions upon the hands when milking cattle so affected. One of these men had a well-marked vaccinia scar as the result of such a pustule. Dr. Martin further made some interesting comparisons of the course of the vesicle in the cases inoculated from this new virus and that in inoculations from the well-known Beaugey stock. The vesicle from the Cohasset virus is slower of development. He urged the importance of studying the changes in the vesicles between the tenth and thirtieth day after vaccination, in order to arrive at a correct appreciation of the value of one inoculation. The vesicle from humanized virus develops more quickly, but not so completely as that following inoculation from the cow. At the close of Dr. Martin's remarks the thanks of the society were voted for his very interesting communication.

PROCEEDINGS OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED meeting, first Thursday of June. President WILLIAM W. WHEELER in the chair.

J. J. CAMPBELL, M. D., of Baltimore, honorary member, communicated a paper entitled

CAPABILITY OF UTERINE LESIONS TO SUPERINDUCE SCLEROSIS OF THE CORD AND PARALYSIS.

The general argument of the author was to the effect that as lesions of nearly every other organ and tissue may originate sequentially to uterine disease, it is right to assume that sclerosis may and does so orig-

inate. In electricity was placed the chief dependence both for the diagnosis and treatment of sclerosis. A discussion followed the paper, in which Fellows quite generally took part, the general purport of which was to the effect that while there was much of interest in Dr. Campbell's paper, the actual relation of uterine disease and spinal disease was not proven, nor was it established by the experience of the profession.

RUBBER SURGICAL APPLIANCES.

H. O. MARCY, M. D., offered to the society the exhibition of certain rubber surgical appliances: first, an ice-cap, made of connected rubber tubing, and calculated to allow of a continuous current of ice-water about the head. Had intended to have a similar apparatus made for him by the Davidson Rubber Company, when this was placed in his hands, originated, as he understood, by Thornton, of London. In a case of meningitis the patient had demanded its continuous use for twenty hours out of the twenty-four, and this had been kept up for a fortnight. Another device consisted of firm rubber tubing connected together to form a kind of oval-shaped mat, designed to rest under the patient's back or lie upon the abdomen, and provide a constant stream of cold water; would serve as well for hot water. A drainage pipe, at distal extremity, conveyed the water away. Also a kind of rubber bed-pan, much enlarged, convenient for the vaginal douche, and, equally, for use in uterine or rectal surgery. The doctor also showed various sizes of double drainage tubes, adapted both for washing out the stomach, bladder, and any artificial cavity.

DR. H. A. MARTIN objected to the drainage tube, as usually made, as containing sulphide of antimony, which made the rubber brittle and rendered possible its sudden snapping and breaking off while in use in stomach or bladder. The doctor also referred to a recent modification of the rubber catheter which had its orifice in the extreme distal extremity.

DR. MARCY approved of this, especially in case of enlarged prostate, as the firmness of the tube was not weakened, as with the fenestrated catheter, at just the point where it should be especially firm when it is being pushed through the narrowed canal. Occasionally, however, it will happen that the hole in the end of the catheter will catch for an instant in the mucous membrane as it is being withdrawn, occasioning considerable pain to the patient.

On call for

PATHOLOGICAL SPECIMENS

DR. MARTIN exhibited, with following history, a rounded tumor mass removed the week before from a woman sixty-two or sixty-three years old; had passed menopause fifteen years; had suffered greatly from fibroid tumors of the uterus for twenty-five years previous to cessation of menstruation, and had had a corresponding history of menorrhagia and anæmia; had long been annoyed by present tumor, but had refused all interference, but this resolve had been lately abandoned on account of the extreme pain the growth occasioned, especially on motion. Examination revealed a hard mass just under surface of abdomen, to left side, near region of ovary, very movable, and seemingly just below integuments, external to peritonæum, and unconnected with uterus. Pressure and movement of tumor gave great pain. In beginning to operate had in mind a similar growth he had previously

removed from the nates of a boy, and which was attached to a glutæus muscle.

Dissected down carefully, seeing nothing like serous membrane, and had reached the capsule, when he suddenly found himself inside the peritoneum, and tumor instantly disappeared. Enlarged the incision, found tumor, and enucleated with finger. Patient, in giving her history, said that as much as seven years ago she first observed a small growth of the size of a filbert near the left groin, and this had been growing since. Last four or five months it had greatly changed in character, had hardened and developed nodosities, to which change was attributable the increased suffering the tumor occasioned when it was moved. It was probably at first a much larger fibroid, but it had degenerated, had become in a measure calcified, and so had shrunk, and its roughness of surface become more and more apparent. Probably had developed from the broad ligament. No hemorrhage, except from one small vessel, which gave a good deal of trouble. Tumor so hard that it had to be cut through with a saw in order to divide it.

In this connection, Dr. Martin referred to strictures he had previously made in respect of meddling with uterine fibroids so long as the patient's condition does not present an absolute demand for their removal. Similar ground was taken by Tait in an article published in the *American Annals of Anatomy and Surgery*, just issued.

Dr. WEEKS asked Dr. Martin if the operation was done antiseptically. Reply: It was not; had never operated in this way, and never should. He would distinguish, however, between a proper regard for cleanliness, including free washing and bathing with carbolic acid, and the paraphernalia of the antiseptic system, which was founded on the germ theory, and equaled in its absurdity the old "doctrine of signatures."

A question by Dr. W. S. BROWN elicited the information that the operation was but little retarded by adhesions, and the enucleation had been wholly accomplished by the fingers without aid of the knife. Dr. Martin further remarked of antiseptic surgery that, had he used this method at the beginning, he should probably have so continued, and grown to be among its enthusiastic adherents, for his results could hardly have been better otherwise, in certain departments, than as now presented, and it would have been but natural to give the praise to antiseptics. He was now about to go to London to report his results in over one hundred and fifty tapings of synovial membranes for effusion into joint-cavities, chiefly the knee. It was his practice to let the patient walk away within ten or fifteen minutes after the puncture, and his success had been quite uniform. Had begun otherwise; had supposed patient ought to remain still a considerable time after the operation, but with further experience he had come to believe that he was rather better for the walk home.

Dr. NORTON showed specimens of monstrosity, with following history: Patient had been previously confined six times, in all of which confinements but the last he had attended her. Last confinement at full term five years before; eldest child a deaf mute. Specimen was the result of a recent miscarriage at six months, a twin pregnancy. One child normally developed, the other a monstrosity, with following features of prominence, namely, hydrocephalus, left arm want-

ing, right immensely developed, left eye and ear lacking, hare-lip, exstrophy of abdominal viscera.

Dr. MARTIN reported a case of so-called hydatids, in which an immense quantity of this growth had been developed synchronously with a fetus up to six months. In another case, that of a male, he was summoned in haste because patient was in terrible distress from inability to pass his water. Had got relief before his arrival; after brief intellectual straining a large cyst came away, and this was immediately followed by smaller ones in sufficient quantity to fill a basin. This happened twenty-five years ago; the man was still living, and had had no trouble since.

CLITORODECTOMY.

Dr. MARCY presented the specimen from an operation for clitorodectomy. Patient, a German, fifty-four years of age, had had a number of children, and was of very nervous temperament; menstruation ceased about ten years ago. A few years before, suffering from irritation about the vulva, she was sent to the Massachusetts General Hospital, and there the urethra was dilated, but without affording relief. When first seen by Dr. Marcy there were urethral caruncles, which were removed and have not returned, but the vulvo-vaginal irritation was in no wise lessened. She represented she was constantly teased with sexual excitement to such extent that life had become a burden. Sleep, without opiates, was the exception; appetite very seriously impaired. There were periods of excitement and depression, of hysterical weeping, and she was thought by some members of her family to be insane.

She had taken up with avidity a distant suggestion that the clitoris might be removed, and the family were earnestly in favor of it; glad to have anything done that might afford relief. The doctor further said he had found but little in the books to guide him in performing the operation. Baker Brown, whose name and fame were unhappily associated with the removal of the clitoris, did not describe his method in his book. The doctor said he made a free dissection from about one half inch anterior to the gland, and dissected the crura at about the same distance upon either side of the bifurcation. Encountered more hemorrhage than he had expected, chiefly from the division of an artery on both sides, which was about two thirds the size of the radial. Was obliged to pass a ligature around each crus. The lips of the wound were carefully approximated, convalescence was uninterrupted, and union by first intention was obtained. Had brought to the meeting a clitoris, presumably healthy, which he had dissected from a subject of autopsy. The clitoris of clitorodectomy was shown to be much the larger, but it was not certain the increased size was evidence of disease, as nature allows considerable latitude in respect of the size of this organ, as also of the penis. Dr. Marcy added, in conclusion, there was still a difference of opinion as to the nervous centres which controlled sexuality, many believing that, in the female, the ovary was the principal source of such influence. This could hardly be true in the case reported, as the ovarian function had long since ceased.

Dr. BROWN suggested that Battley's operation would have been more appropriate.

Dr. MARCY admitted this was a mooted point. Dr. Thomas had recently operated upon a young married woman of extreme nervous temperament and long

given to masturbation, who was crazed by every effort on the part of her husband, to such extent that his life had been more than once attempted, as on one occasion with a razor. The doctor removed the clitoris down to the rami. In a case which Dr. Marcy had reported to the society, and of which he had exhibited the specimens, where more than one year ago he had removed both ovaries, sexuality had in no wise lessened. Menstruation has also continued quite regularly, and at times in quantity sufficient to greatly weaken the patient.

DR. MARTIN gave the points of a case of a man who had consulted him for seminal emission. The penis had become so sensitive that friction of the clothing would cause orgasm and seminal discharge. Demanded circumcision, and the doctor acceded to the request. In this operation had used a peculiar kind of forceps which were invented by a Jew. They had given him considerable trouble in their working, but he was pleased with the result of the operation. A ribbon-like section of the prepuce was removed, and the wound healed kindly, leaving no apparent cicatrix, and no redundant tissue or awkward scar, as was so often done by the usual method, requiring a subsequent trimming to give the organ a respectable look.

Society adjourned.

Recent Literature.

Supplement to Ziemssen's Cyclopædia of the Practice of Medicine. Edited by GEORGE L. PEABODY, M. D. New York: Wm. Wood & Co. Pp. 844.

Most practitioners in the United States are sufficiently familiar with Ziemssen's Cyclopædia to be aware that some of the volumes are much older than others, and that all of them need some additions to bring them up to the present status of the specialties of which they treat. The work before us is for the purpose of doing this, and has been written by twenty-eight American physicians. An attempt to criticise it, therefore, as one is supposed to criticise a book he knows all about, involves the assumption that the critic has himself gone over all the ground covered by the aforesaid twenty-eight, the inherent improbability of which feat is so great as to suggest even to the most learned reviewer that he had better confine himself within much narrower limits. It is obvious that bibliography must form a very important part of such a book, and this department seems to have been thoroughly cared for, the number of references being very great, and in those portions where the writer is able to judge from his own reading very complete.

It is to be regretted, however, that one very important series (that upon syphilis) was omitted for want of room. It would have been worth while to sacrifice for such a purpose the sub-title pages, of which there are many, and one could here and there pick out some pages even of the text which could be better spared. The articles based upon these references and upon the writers' own views naturally vary a good deal in their character, in some being but a brief *resumé* of the more important articles, while in others a more serious attempt at coördination and logical arrangement is made. The latter we cannot help considering, when the writers are so judiciously selected, as by far the most valuable. Nearly every article, however, is to

be commended as thorough and sensible. A notable exception, however, is to be found in the very important subject of diseases of the female sexual organs, which we cannot help thinking (though without opportunity of reference to the original) is but little more than a translation of some of the passages contained in the second German edition of Ziemssen and not in the first. It must be almost worthless to American practitioners.

In speaking of perimetritis, to which four and a half lines are devoted, if the statement that "if an abscess points externally it should be freely opened, injected with carbolized water," etc., represents the progress made since the last edition, what must have been the status of this branch of gynecology at that time. Our suspicions of the method of preparation of this article are strengthened by the fact that when spring waters are mentioned they are all German, and the tincture of iodine spoken of is marked Ph. Bor.

Fancy the feelings (and language?) of the "busy practitioner" who is in a hurry to learn the latest thing that has been suggested for that most annoying symptom, pruritus vulvæ, and finds, on consulting this volume *only*, "When the pruritus is a symptom of diabetes, a course at Carlsbad offers the best chance of cure."

Many suggestions are offered by such a book beside those strictly connected with the subjects treated of.

Obvious as it must be on looking over the bibliographical lists how largely medical science depends on the untiring German patience, a comparison of this volume with its predecessors will at least show (and especially to those who helped translate the earlier ones) that in *telling* what they know the American authors are at no disadvantage, and that their clear and condensed style contrasts (to us at least) most agreeably with the complacent verbosity of many of the original writers.

This volume is a most important and useful addition to the series.

Prompt publication adds greatly to the value of articles of the character of those which make up this series, and it is said that a year has elapsed between their receipt by the publishers and the appearance of the book. It is but fair to the writers that this, if a fact, should be known.

— In the eleventh Annual Report on the Health of Salford for the year 1879, Dr. Tatham gives a striking illustration of one of the modes of spread of scarlatina. The source in this case was found to be a pawnbroker's shop in the affected district, where people were in the habit of pawning such of their clothes as they can spare early in each week, taking them out again on Saturday when the weekly wages were received.

The premises of this shop consisted of three rooms, the outer two of which were used as shop and store-room, and the inner as a living room. In this last a large quantity of pawned bedding, etc., was deposited, and here was found a child recovering from scarlet fever. There was free access between this room and the outer rooms. The patient was removed, and the house and stock in trade thoroughly disinfected, after which the spread of the fever ceased. — *Sanitary Engineer.*

Medical and Surgical Journal.

THURSDAY, AUGUST 11, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 1 PARK STREET, BOSTON, MASS.

VACCINATION OF CHARBON.

At a recent meeting of the French Academy of Medicine (June 21, 1881) M. Bouley made a statement of Pasteur's experiments with the virus of charbon, a disease peculiarly fatal to sheep, and of the results at which he has arrived with the protective inoculation of a modified virus. To judge by this statement and the result of experiments since reported, there seems to be no question but that Pasteur has succeeded in formulating a law for the preparation of a thoroughly protective charbon-vaccine and of explaining the various stages of the process. Previously M. Toussaint, the veterinarian, had found by experiment that the defibrinated blood of a sheep attacked with charbon, if exposed from ten to twenty minutes to a temperature of 55° C., lost the excess of virulence which renders the blood as originally taken fatal, while still retaining sufficient energy to transmit a mild charbon fever upon inoculation, by which immunity is acquired against the disease.

This fact was established by more than forty experiments, but Toussaint did not arrive at any exact formula for the preparation of the vaccine virus, and, moreover, the results of his experiments were to a certain extent contradictory of those of Pasteur with the virus of chicken cholera, inasmuch as the behavior of the two germs upon exposure to the air was quite different.

The virulence of the microbion of chicken cholera was found to be in inverse ratio to the length of its exposure to fresh air; the microbion of charbon, on the other hand, was in no wise affected by such exposure, preserving its activity for months and years. M. Pasteur suspected that this difference depended upon the different modes of propagation of the two organisms, and this he eventually found to be the case. The microbion of chicken cholera propagates itself solely by fissure, there are no spores, whilst the microbion of charbon has two ways of generation, — by fissure and by spores.

Now although the substance proper of the mycelium of charbon is easily affected by the air, the spores resist all exposure. These, however, can be destroyed by more active agents, such as heat. Pasteur found that at a temperature of 12 or 13° C. the bacteria of charbon continue to generate by fissure, but no longer produce spores. By keeping the culture-liquid at that temperature and exposing the mycelium engendered to the action of the air, he found that it gradually lost its virulence in the same manner as did the cul-

ture liquid of chicken cholera, and the poison assumed a mild character compatible with life when employed for inoculation.

Pursuing this line of investigation Pasteur found, moreover, that the microbion which has lost the power of producing spores in a hot medium will resume this power if transferred to a cold one, and that these spores born from a mycelium enfeebled by exposure to heat possess only a modified virulence, exactly proportioned to that of the parent mycelium.

Pasteur seems to be justly credited with having succeeded in discovering the conditions of life of the micro-organisms constituting the poison of charbon, in directing their development according to a pre-arranged plan in such a way as to reduce their activity to any desired degree; in short, with having succeeded in making with certainty, at pleasure, of a deadly organism one which is benign, and which will by inoculation confer immunity against the effects of the other. These pretensions are now supported by a large number of confirmatory experiments performed by a variety of competent investigators. Were the practical confirmation of these principles to be confined merely to the control of so destructive a malady as charbon has proved among sheep, the result would be sufficiently important, but the probability of their wider application is sufficiently great to give good cause to expect much more extended and beneficent consequences in the not distant future.

STATE MEDICAL SOCIETY JOURNALS.

UNDER the title of the *Ohio Medical Journal* the *Ohio Medical Recorder* has become the journal of the Ohio State Medical Society, and will in future take the place of the usual volume of Transactions. The editor in charge is the secretary of the society, and was formerly managing editor of the *Recorder*; he is to be assisted by four associate editors from as many of the larger cities in different parts of the State.

It is estimated that the proceedings of the Society will by this arrangement have a circulation of three thousand copies instead of less than five hundred, as under the old method. We believe the Ohio Medical Society will not regret this step, which it is, if our memory serves us, the first State society to take. The arrangement adopted is practically on a small scale that existing between the British Medical Society and its Journal, a connection, which has been for a number of years entirely satisfactory to all concerned. The adoption of such an arrangement for publication was urged, as our readers will remember, upon the American Medical Association year before last at its meeting in New York by its then President, Dr. Sayre, and we have ourselves called attention to the advantages of such a method of publication from a considerably earlier period.

Some drawbacks have been pointed out and others may present themselves, and the success of such an arrangement must, of course, depend largely upon the vigor and tact of the occupant or occupants of the offices of secretary and editor.

We shall watch with interest the results of the connection between the Ohio Medical Society and the *Ohio Medical Journal*, which we have little doubt, unless some unforeseen complication should arise, will result in the infusion of new life and activity into each. The members of the Society, on the one hand, will at least be sure of prompt publication and of a larger and more critical audience; the *Journal* of the Society, on the other, will have a certain *clientèle*, each one of whom will be at once a reader, a subscriber, and a possible contributor, having a personal and general interest in its welfare and improvement.

MEDICAL NOTES.

— The vital statistics of the city of New York for the first quarter of 1881 offer some curious and interesting figures, from among which those bearing on the relative proportion of the native and foreign population are not the least so. During this quarter 2228 couples were married in the city. Of the 2228 men only 1003 were natives, leaving 1225, or 55 per cent., of foreign birth. Of the 2228 females 1218, or 55 per cent., were natives. Of native males 844 took native wives, so only 37 per cent. of the 2228 couples were natives on both sides. The other native-born grooms took 49 German, 42 Irish, 32 English, 6 West Indian, 5 Canadian, 4 Austrian, 3 French, 3 Scotch, 2 Polish, and 1 each of Belgian, Danish, Low Dutch, Swiss, Australian, Isle of Guernsey, and Prince Edward Island women. Of the native-born brides — 1218 in all — 844 took native husbands, 204 married Germans, 47 English, 41 Irish, 9 Scotch, 9 West Indian, 7 Austrian, 7 Russian, 6 Polish, 5 Canadian, 5 Bohemian, 5 Italian, 5 French, 4 Danish, 3 Swiss, 3 Spanish, 2 Belgian, 2 Hollandish, 2 Norwegian, 2 Swedish, 2 unknown, and 1 each of Welsh, Portuguese, Turkish, and Australian. So, within the first three months of the year, New York girls formed alliances with twenty-four countries beside their own. From such an intermingling of races and nations there naturally follows an exceedingly mixed race of descendants. More than one half of the city's population is rated as "native born." But upon examination for "natives" pure and simple — that is, natives of native parentage — the figures shrink surprisingly. Thus it appears that of 6832 children born in the three months under consideration, only 1796 had Americans for both father and mother. Native-born mothers had 1031 children by foreign fathers, of whom 523 fathers were German, 212 Irish, 94 English, 66 unknown, 22 Canadian, 19 Scotch, 13 Italian, 11 French, 10 Austrian, 8 Swedish, 8 West Indian, 7 Spanish, 6 Polish, 6 Russian, 5 Hollandish, 5 Swedish, 5 Bohemian, 3 Danish, 3 Welsh, and 1 each of China, Canary Islands, South America, and Turkey. Here are twenty-four countries besides our own represented. Of mixed parentage there were a considerable number, of course, as in the case of American mothers, who had 2827 children, of whom 1796 had native and 1031 foreign born fathers. There were 1624 children whose fathers and mothers were Ger-

mans, 523 of American mothers and German fathers, and only 83 of American fathers and German mothers. Irish mothers gave 1122 children, 821 of whom were of full Irish blood, 170 half American, 43 half English, 28 half German, 17 half unknown, 11 half Scotch, etc. Children of English mothers numbered 209, of whom only 66 had English fathers, 67 American fathers, 31 Irish, and 18 German.

— We notice in the *Medical Press and Circular* that the Rev. W. K. Hobart, of Londonderry, an ex-scholar of Trinity College, Dublin, is about to publish, by subscription, a work showing, from internal evidence, that the "Gospel according to St. Luke," and the "Acts of the Apostles," were written by the same person, and that the writer was a medical man. The work consists of an examination of words and phrases peculiar to these parts of the Bible, compared with the use of the same words and phrases in the works of the Greek medical writers, namely, Hippocrates, Aretæus, Dioscorides, and Galen.

— The *Medical Press and Circular* quotes an American surgeon, who is in England for the purpose of attending the International Medical Congress, on the subject of literary plagiarism, as follows: "Few of us pretend to write anything original; we either have n't the time or we have n't the mind. You Europeans leave us nothing to do, and so instead of pretending to take you down a stripe we take a book that we guess will suit our purpose, make a few foot-notes, and stick another name on the title-page. The book is none the worse for it, and its new author is helped like a lame dog over a tall stile."

— Dr. Burq, well known for his researches on metallotherapy, lately drew up some statistics, which he culled from different military hospitals, to show the influence of wind-instruments on pulmonary affections; and he remarked that pulmonary phthisis was much less frequent among the bandsmen who played on these instruments than among those who played on others; he therefore concludes that, as a preventive measure, persons threatened with phthisis ought to be made to sing, and to use their voice more than is generally done. Dr. Burq has constructed an apparatus by which the capacity of the lungs for inspiration or expiration can be measured; but I doubt whether his experience about wind-instruments would tally with that of our military surgeons; or whether his recommendation for the preventive cure of phthisis would be received with much favor by the generality of British physicians. I have just read in a medical paper the following anecdote bearing on the subject. A certain hospital physician, having notions opposed to those expressed by Dr. Burq, always made it a point to question his phthisical patients as to their musical practices. At his hospital visit one morning, a cachectic-looking patient, who was in the last stage of consumption, went to consult him. "What is your profession?" asked the doctor. "Musician, sir," was the reply. The doctor, turning to the students who were about him, observed, "What did I say? Here is a remarkable example of phthisis in those who use wind-instruments. What instrument do you play on?" continued the doctor.

"The bass drum," was the patient's reply. You may imagine the doctor's confusion; and, as the article adds, it is to be hoped he was forever cured of his etiological conceit. — *Paris Correspondent British Medical Journal.*

PHARMACEUTICAL NOTE.

ADMINISTRATION OF TANNIN.

—According to a recent article by Dr. Lewin in Virchow's *Archiv* it should be borne in mind that when tannin enters the stomach it forms with albumen precipitates, which require for their solution an excess of albumen, of lactic, or of hydrochloric acid. If the albuminate be not soon dissolved, especially if the tannin has been given in the form of a powder, the solid particles are likely to adhere to the gastric walls, and produce extensive irritation of the mucous membrane. To avoid this the tannin should be given either as a solution of albuminate of tannin or as alkaline tannate, and not in the form of a powder. A solution of albuminate of tannin is readily prepared by adding a solution of albumen to a solution of tannin till the precipitate at first formed is redissolved in the excess of albumen. This, if made alkaline by the addition of soda carbonate, is still more readily absorbed.

Miscellany.

ACUTE SUPPURATIVE ARTHRITIS IN INFANTS.

MR. G. A. WRIGHT, Surgeon to the Hospital for Children, Pendlebury, gives in the *Lancet* an instructive account of three cases of the above disease:—

The disease of which the following cases are instances is one of which I think inadequate descriptions are given in discussing the affections of joints in children, and of which Mr. Thomas Smith has alone, as far as I can discover, given us a really complete account in his paper in the St. Bartholomew's Hospital Reports for 1871; and yet it is a condition which cannot be very rare, as Mr. Smith records twenty-one instances of it, and speaks of them as a selection only out of a larger number, while the great fatality occurring among these cases, and the urgent need for prompt treatment, make the recognition of the tendencies of the disease all-important. The affection is that of primary or acute suppurative arthritis occurring in infants at any time during the first year of life, or thereabouts. The disease is acute in its onset; it generally affects but one joint at first, and it produces great depression of the child's powers; it is exceedingly destructive, not only to the joint, but to the ends of the bones forming the articulation, in which, indeed, the lesion originates.

CASE I. Hannah H., eleven weeks old, was admitted under my care into the Hospital for Sick Children at Pendlebury, on October 8th, 1880, with the following history. When fourteen days old, a swelling was noticed in the end of the left leg; this disappeared, and the child was then said to have had an attack of erysipelas of the thigh and groin, and then the inflammation seemed to focus itself in the left knee, below

which an opening formed, and from this discharge had escaped up to the time of admission. The child had been suckled and had had no injury or other illness. There was no history pointing to syphilis. On admission the left knee was much swollen and very painful. Just below and in front of the joint was an opening discharging pus; this led down to a softened patch in the head of the tibia. The child was very ill and marasmic, and its temperature rose at times to above 103°. On exploring the sinus, soft carious bony detritus was felt and gouged away from the upper part of the bone, and it was found that pressure upon the knee joint caused pus to well through an opening in the articular surface of the tibia into the wound. The joint was then freely incised on each side of the patella, and a drainage tube passed through it. During the first twenty-four hours the child had carboloria, after this it improved a little for a day or two, but again sank, and died on October 21st. On examining the knee, the joint was found to be completely disorganized, and the upper end of the tibia destroyed.

CASE II.—Martha R., aged thirteen months, was admitted on October 1st, 1880. Two months before admission the child had measles, followed by temporary albuminuria, but soon completely recovered. One month later pain and swelling appeared, extending from the hip to the knee. Fourteen days before admission she became feverish, with vomiting, and much pain in the limb. There was no history of injury; the family history was good; the child had been suckled and had never walked. On admission she was very anæmic and worn; there was great swelling round the right hip, reaching up to the buttock, into the groin, and over the lower part of the abdomen, where fluctuation was well marked; the superficial veins were much distended. On October 7th the abscess was opened antiseptically, after the child's condition had been somewhat improved by careful feeding, and six or eight ounces of pus escaped. On exploration with the finger the head of the femur was found to be exposed and rough, and the joint entirely disorganized; the wound was washed out with carbolic acid (one in forty). There was no bleeding of any importance. The same night the child was collapsed and carboloria appeared; this, however, passed off the next day, and up to the 15th she improved somewhat, but there was still free discharge, which was exhausting her; and on the 17th the upper end of the femur was removed, and a small, rough, carious button of bone, covered with granulations, was found to be the only representative of the head and neck of the femur. The operation was antiseptic. From this time the child did uninterruptedly well, and rapidly gained flesh and strength; and on November 16th the wound had entirely healed, and she is now (November 28th) well, and has considerable power over the limb, which is barely half an inch shorter than the sound limb.

CASE III.—Anna B., aged nineteen days; admitted November 5th, 1880. The child was said to have been healthy at birth, but fretful. It was suckled, and there was no syphilitic family history. The account stated that it was a "cross birth," and the mother was attended by a midwife, who "helped" the labor. A day or two before admission the child was apparently in pain, and vomited; and on November 4th a swelling was noticed round the right shoulder.

On admission a large fluctuating swelling, without much redness, was found surrounding and obscuring

the right shoulder. The child seemed to be fairly well.

On November 6th the abscess was opened antiseptically, and carefully explored with the finger. A large sac was found surrounding the front and outer side of the joint, but no communication with the interior of the joint could be felt, and it was concluded that the abscess was probably peri articular, and due to some violence used by the midwife at the time of its birth.

The child went on well until November 16th. There was no heat or tenderness about the shoulder, but it discharged rather freely. The temperature ranged not higher than 100.4°, and the abscess nearly healed. On the 17th a slight swelling was noticed over the right parotid region, and this proved to be an abscess; and on the 18th an abscess appeared over the lower part of the sacrum. Temperature 101.6° to 99.6°. The child took its food well, and did not seem very ill. The abscess over the parotid was aspirated; the one over the sacrum left alone. On the 19th, a large abscess was found round the left hip and upper part of the left thigh; the whole leg below was cedematous, and roughness could be felt on moving the joint. Temperature 98.6°. She still took her food well, but was pale. On the 20th the abscess over the left hip was opened antiseptically and carefully explored; no communication with the joint could be felt. The facial abscess refilled, and on the 24th discharged through the ear. There was a great deal of discharge from the hip, which looked unhealthy and was septic. There was much induration round the wound and neighboring parts. The child went on in much the same state till December 4th, the opening in the shoulder having entirely healed, and no fresh abscesses appeared. The child then got worse, and was sick and refused its food. This and the unhealthy condition of the hip induced me to explore the wound afresh; and so, under chloroform, the wound was examined, and the joint felt to be rough and disorganized. The upper end of the femur was dissected out and removed with a scalpel. No trace of the head of the bone was left; a small hollow in the upper part of the great trochanter, with a few little bony granules upon it, was all that represented the head and neck of the bone. There was very little bleeding, but the child was very low. In the evening it took its food and was quiet. On the 6th there was some carboluria; the child was pale and weak, and vomited twice. During the next two days it sank, in spite of stimulation and careful feeding, and died on the 8th. The carboluria lasted only a few hours.

Necropsy.—On examining the hip, the wound was found gray and sloughy; the upper end of the femur was unhealthy. The acetabular cartilage was soft and discolored, but not eroded. The child was much wasted, and scattered about the body and limbs were numerous cutaneous pyæmic abscesses. On exposing the right shoulder the joint was found completely gone, and no trace of the head or neck of the humerus remained. Some repair had taken place, and the wound was soundly healed over the joint, which contained no pus. The abscess over the parotid was empty and healed. The abscess over the sacrum communicated with the lower sacral joints, which were disorganized. In the abdomen some recent lymph was found coating the spleen, but no other peritonitis. In the liver were two pyæmic abscesses, one immediately beneath the capsule, and the other rather deeper. In the right

kidney was an abscess occupying almost the whole of one pyramid, and the corresponding amount of cortex. The upper lobe of the right lung was pneumonic, and there were scattered patches of pneumonia with abscesses throughout the rest of the lungs. The brain was not examined; there was no pus in either knee-joint.

Mr. Holmes, and more particularly Mr. Smith, have pointed out that the disease frequently, if not always, begins as a subarticular osteitis, which often penetrates the joint, and of this Case I. was a typical instance. Mr. Smith, as well as other writers, point out the difference between this disease and the so-called "syphilitic decapitation of the epiphyses," or "syphilitic telostitis," in which the seat of the disease is between the epiphysis and diaphysis, and abscess may or may not occur, while many bones are affected. In the three cases here recorded there was no evidence of any syphilitic taint. A noteworthy point in these cases, alluded to by Mr. Holmes, is the great extent of the primary inflammation, which seems to attack a large area of the limb before it concentrates itself upon the particular joint, and this gives rise to the question whether it is possible that the lesion is primarily a general phlebitis of the limb, in which the veins of the bones are involved, whilst the centre of ossification of the epiphysis, being one of the most vascular parts in the neighborhood, suffers most, for there seems to be little doubt that the disease is a true osteitis, and that the joint affection is secondary by extension.

Of the twenty-one cases recorded by Mr. Smith thirteen died, and in none of these was any operation, except opening the abscesses, performed; in the others more or less useful limbs resulted without further operation, but I cannot help thinking that in these cases the amount of repair required, if the diseased part is not removed, makes too great a demand upon the already over-taxed powers of the child, and that the results would be better if the disorganized bone was removed and the progress of the disease arrested. As to the ætiology of the disease, in four of Mr. Smith's cases there was a history of injury, and in one of scarlatina. In one of my own cases there was a history of measles, and in another of possible injury; but there appears no doubt that the disease most commonly arises spontaneously. The drawback of the depressing effects of carbolic poisoning was felt in all these cases, which seem peculiarly susceptible to it, though there was no albuminuria.

INJURIES OF THE HEAD.

BY WILLIAM MAC CORMAC, F. R. C. S.

THE following interesting article on the treatment of injuries of the head is a portion of an address delivered before the South Western Branch of the British Medical Association.

"I remember about five years ago a distinguished member of the Court of Examiners of the Royal College of Surgeons saying to me, he had asked a candidate the following question: "Under what circumstances would you trephine the skull?" and the candidate replied, "Never." I remember thinking that though the candidate was perhaps a little too positive, he was in the main right, and that if one rule were to be adopted or followed in every case, the foregoing was the right one. My experience in the war of 1870

impressed me strongly with the comparative advantages of non-interference in gun-shot fracture of the skull, for I believe every one who had been operated on by the trephine or elevator died.

"For many years past the general experience of the disastrous results which commonly ensued upon the operation of trephining, led to its abandonment, except in a very limited class of cases.

"The practice has been, not to trephine in compound fractures, even with depression, unless this was accompanied by symptoms, except perhaps the fracture be a punctured one. Under no circumstances, was it always taught, ought a simple depressed fracture to be converted into a compound one. . . .

"Now, although it be quite true that some cases of depressed fracture, both with and without symptoms, do well without operative interference, I do not think that this practice, if invariably carried out, will produce such desirable results, immediate and remote, as we may now expect with the aid of the improved antiseptic method of treatment.

"Almost any degree of head injury, we know, may be recovered from, but we must not from this assume that head injuries are unimportant.

"From time to time startling and almost incredible instances of recovery after head injury are published. In the records of military surgery there are many such. . . .

"In a patient under my own observation, a long nail, which had been used as the ramrod of a pistol, was shot into the forehead, passing right back for at least two inches through the anterior lobe of the brain. The boy walked a couple of miles with the nail sticking in his head; and when I removed the nail, twenty-four hours afterwards, brain substance exuded. The boy recovered, with some slight mental deficiency. This, as Professor Ferrier states in his work on the localization of cerebral symptoms, is a common sequence of injury of the frontal lobes of the brain.

"But cases such as these do not in the least affect the general question of how best to obtain the greatest surgical good for the greatest number; and I must now say that I endorse, as in my opinion true, all that your President says in the very interesting and instructive Address which he read before this branch in 1877. He tells us it has been the invariable practice of surgeons in this district, to elevate depressed bone in compound fracture of the skull, without waiting for symptoms, and that recovery is the rule, due perhaps in a large measure to the pure antiseptic breezes from the great ocean beside you. Septic influences here are doubtless at a minimum, and I can well appreciate the advantage of trephining in cases, many of which, from the manner of their production, by small bodies falling from a height upon the head, much resemble punctured fractures. Dr. Hudson has also told you, in his Address, how rare the operation of trephining had become in our great London hospitals. He is right in so saying; and also, I think, in further stating that of late years the operation is again coming more or less into general favor.

"He quotes, with approval, the opinion that it is the surgeon's duty to trephine at once in punctured fractures of the skull, without waiting for symptoms of irritation or compression.

"I am sure that this is correct, and that he who waits under such circumstances waits until it is too late, or

until he must operate under conditions much less favorable. For when symptoms of irritation, compression, or inflammation of the brain and its membranes supervene after some interval from the date of injury, and this is a frequent experience in compound fractures of the skull, at any rate when antiseptic precautions have not been adopted, it is often too late to do good by operative interference, and quite irrespective of it, the symptoms generally progress to a fatal issue.

"In every case where trephining or elevation of depressed fragments is performed for injury, I believe that it ought to be determined upon and performed regardless of the presence or absence of symptoms. The primary disinfection of the wound is often otherwise impracticable. Indeed, the question much resembles the greatly debated one of the comparative advantages of primary amputation and secondary amputation. We have, long since, finally decided upon which of these is the better, and I feel sure, for reasons, some of which are not very dissimilar, that when trephining for injury is likely to be required at all, it must also be primary in order to be successful. The cases in which trephining is most needed and most useful, are those in which the forces productive of fracture mainly exhaust themselves in causing the local bone injury, without seriously compromising the general brain mass.

"Small bodies, such as stones or bullets, striking the skull with a high velocity, often produce typical instances of this kind of injury, and I feel assured that, if performed with antiseptic precautions, the immediate removal of fragments of splintered skull is the better course to pursue, whether these occasion immediate brain symptoms or not.

"The chances of subsequent meningitis and brain inflammation are thus minimized, and the patient is, to a large extent, protected from the too frequent results of depressed fracture, which, when healed in this state, is apt to result in many cases in violent headache and neuralgia, partial paralysis of the extremities, and even of the organs of sense, with perhaps epileptiform seizures.

"Further, when I had good reason to suspect that the skull was comminuted and depressed, I should not hesitate, in certain cases at least, to cut through the unbroken scalp, expose the seat of injury in the bone, and thus convert the simple fracture into a compound one. I would do so, believing in the efficient protection which antiseptic precautions afford, and because I should thus hope to give the patient a better prospect of complete recovery and of future health.

"I have returned, therefore, to a practice, though with some differences in the manner in which it is carried out, as advocated by Mr. Pott a hundred years ago. . . .

"Experiment, as well as experience, sufficiently justifies our reliance upon the security that the antiseptic method affords in injury of the head.

"Professor Gerald Yeo, for example, thus terminates a note upon his interesting series of experiments on the trephining of monkeys, the animals nearest to man in respect of septic receptivities, their behavior under chloroform, and the influence which operative procedures exert upon them.

"Among the cases treated antiseptically," he says, "there was not one case of inflammation; and where the antiseptic method could not be had recourse to, there was intense encephalitis — in short, one hundred per cent. of those cases treated by antiseptic dressings

recovered without inflammation; while without antiseptic dressings, one hundred per cent. perished of acute encephalitis."

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THIS exhibition, which the Executive Committee of the Parkes Museum in London has been organizing since the beginning of the year, was formally opened Saturday, July 16th. The opening ceremony took place in the Royal Albert Hall, upwards of 4300 persons, half the number at least being ladies, were present. It is expected that a handsome sum will be realized for the benefit of the Museum. The secretary of the committee made the following statement:—

"The brief statement I have the honor to make to you on behalf of the Exhibition Committee must, I think, gratify both the exhibitors and the public generally, since it clearly shows that the interest taken in this, the first International exhibition of its kind, has been of an eminently practical character. It was natural that the committee should count upon receiving the coöperation of their own countrymen in an undertaking which could not fail to benefit this country; but they could hardly have expected the large amount of support that has come from the people of other countries. The exhibits are divided into seventeen sections, and they represent almost every industry connected with medicine, architecture, and sanitary engineering. One feature specially worthy of mention is that the work of artisans is exhibited by themselves. Besides the exhibits which have been contributed by London, Dublin, Edinburgh, Glasgow, Liverpool, Manchester, Birmingham, and other large towns in the United Kingdom, the following countries have sent contributions, namely: France, Germany, Austria and Hungary, Italy, Switzerland, Turkey, Holland, Belgium, Norway and Sweden, Bohemia, Bavaria, India, and America. Thanks to the heartiness with which the exhibitors have fallen in with the arrangements made by the committee, the exhibition that you have been invited to inspect to-day is not in an unfinished condition, but is full and complete. It was at first intended that the judges of the different sections should make their awards to the exhibitors on the opening day; but the extent of the exhibition has made it necessary for them to prolong the time for their examinations, and therefore the awards will not be made until next week. The public spirit shown by the subscribers to the guarantee fund should not be overlooked, as without this the committee could not have ventured on an undertaking of such magnitude. With such an inaugural meeting as the present, there can be little doubt that this exhibition will be the means of providing a considerable sum for the Parkes Museum; and at any rate it is sure to stimulate invention and improvement in all that relates to health."

The *British Medical Journal* in a short résumé directs attention to some of the more striking exhibits in Section I. which was devoted to the beds and apparatus shown by the hospitals.

SECTION I.—THE BEDS AND APPARATUS SHOWN BY THE HOSPITALS.

By a very happy thought, the committee of this exhibition were induced to request the metropolitan hos-

pitals to show, in rooms devoted to the purpose, a series of beds illustrating the methods of nursing and treatment in use in the various institutions. The project met with ready response; and the resulting exhibit, now on view in the western gallery (second floor) of the Albert Hall is, we do not hesitate to say, one of the most interesting in the whole exhibition. At first, it was proposed to have living patients to illustrate the various appliances; but better counsels prevailed, and an appeal was made to various eminent artists to lend their lay figures for this purpose—an appeal which was acceded to by Sir Frederick Leighton, Mr. Leslie, Mr. Pettie, Mr. Frith, and many others.

It is impossible to do more than refer very briefly to the apparatus shown, though there are few of the exhibits which would not repay careful study. We may begin with Guy's Hospital, to which a separate room and a lion's share of the beds has been assigned. In one of these beds we notice, as worthy of attention, a specimen showing the method of applying a "Hodgen's" splint (modified by Bloxam and others) to a fractured thigh. The limb is swung in a wire cradle, with flannel understraps, and the long splint, with its elaborate bandages, is entirely dispensed with. In a compound fracture, the wound can be got at without disturbing the limb; and the only drawback is, that a certain amount of lateral movement is permitted between the fractured ends of the bone. In the next bed is seen, applied to the head, an ingenious apparatus (of German invention) for applying cold to any part of the body; a current of iced-water is kept constantly circulating through a system of tubes, made of lead, sufficiently firm to resist the weight of the body, and yet small and soft enough, it is said, to cause no inconvenience to the patient. This apparatus is much used by Mr. Bryant, and may be seen, in various sizes and shapes, in the surgical-instrument department of this Section.

A very neat and convenient cot is shown; and on the opposite side will be found a tracheotomy cot and tent, which is as well suited for its purpose as any other exhibited; though this is, unfortunately, by no means high praise. In this cot we notice Mr. Golding-Bird's "trachea-dilator," made for him by Messrs. Milikin and Down. This instrument consists of two fenestrated blades, which are designed to be introduced into the tracheal wound, and then separated by a screw-action. We have lately had an opportunity of testing this instrument, and can testify to the ease with which it can be introduced, and to the effectual manner in which it keeps open the wound in the trachea, and gives free exit to mucus and membrane. As might be anticipated, the pressure exerted on the two edges of the tracheal wound quickly led to ulceration of the mucous membrane; and for this reason the use of the instrument must, we believe, be limited to the first twenty-four hours. At the end of that time, when hemorrhage will have ceased, and most of the membrane about the chords has been cleared away, its place may be well supplied by one of Mr. Morrant Baker's India-rubber tubes, which are shown in use in a tracheotomy tent exhibited by St. Bartholomew's. This tent is very neat and pretty, and consists entirely of washable materials. It, however, strikes us as rather small, and as by no means perfect; indeed, we hope that one of the salutary results of the exhibition may be to stimulate inventors to design a really suitable tent for this purpose.

Among the other specimens shown by St. Bartholomew's Hospital, is the apparatus for fractured patella, designed by Mr. Manning, as also another method of treating this lesion designed by Mr. Stephenson, a former house-surgeon of the hospital, in which the fragments are retained in position by two broad elastic bands attached to a subjacent wooden cradle. We also notice the contrivance of the late Mr. Callender (commendable for its simplicity) for making pressure on a femoral artery. Fracture of the femur is treated by a long outside (Liston) splint, and extension is made by an ingenious little apparatus, designed, we learn, by a former house-surgeon, Mr. Sankey, and adopted also by the Children's Hospital (Great Ormond Street). This latter hospital exhibits a cot illustrating the treatment of hip-joint disease in general use there. The diseased limb is bandaged to a splint which is supported beneath by an apparatus on the principle of a book-rest, and extension is made as above stated; a long outside splint is applied to the sound limb, and the head only of the little patient is supported on a small square pillow; the child is retained in the recumbent position by the so-called "Queen's Square armlets," a method also made use of in the bed shown by St. Mary's, where it is adapted to a "patient" on whom is also demonstrated the method of treating cervical caries by a leathern collar moulded (by Spratt of Brook Street) to the neck. Leathern splints made by the same firm are also shown in the St. Mary's cot adapted to the treatment of strumous disease of the knee. The collar for cervical caries is supplemented by sand-bags so arranged as to prevent rotation of the head.

The Middlesex Hospital shows the old-fashioned, but very useful, if rather clumsy, De Morgan's splint for the treatment of morbus coxae; and a most convenient apparatus, first used, we believe, by Dr. Cayley, for bathing a fever patient with the least possible disturbance; a hammock slung from a movable gallows receives the patient, who is then raised from his bed by pulleys, carried by a traveler until he is suspended over a bath placed beside the bed, and finally lowered into the bath by a reversed action of the pulleys.

The exhibit of King's College Hospital shows the various apparatus used in the antiseptic treatment of wounds, though we may remark, by the way, that the dressings are only placed in the basket shown when about to be used; it is, we think, unfortunate that one of the tin boxes ordinarily in use for storing the dressings is not also exhibited. We are sorry to find fault, but the tracheotomy-test shown by this hospital, with its heavy flannel curtains and clumsy frame, seems to us singularly unsuited for its purpose, and unworthy of the institution from which it emanates. Neither is the bed shown by University College Hospital worthy of the reputation of that school; we may notice, however, the method of treating Colles's fracture by Carr's splints.

We have nothing but praise for the beds shown by St. Thomas's Hospital. That one which illustrates the adoption of plaster-of-Paris splints (as recently recommended by Mr. Croft in a paper read before the Royal Medical and Chirurgical Society; see *British Medical Journal*, July 2, p. 13) is particularly worthy of careful study, and seems to us the perfection of neatness and simplicity. A cot is also shown by the hospital, which demonstrates the most convenient method of treating hip-joint disease.

We must also strongly recommend to the careful study of our readers the apparatus shown by Charing Cross Hospital. Two beds show the fenestrated splints designed by Mr. Barwell, which are so simple that they can be made by the ordinary engineer of the hospital. The one designed for excision of the knee strikes us as particularly admirable; a back-splint, with broad plates of soft iron moulded to the thigh and calf, reaches from the fold of the nates almost to the knee; the anterior splint consists of three plates moulded to the thigh, leg, and foot, connected together by light iron rods; the heel is left entirely free, and the fenestrum over the knee is sufficiently wide to permit of the easy application of an antiseptic dressing without at all disturbing the splints, which are from the first firmly fixed to the limb by plaster bandages. Another bed, arranged by Mr. Bloxam, shows a "Hodgen's" apparatus, already referred to, as modified by him, and a similar arrangement by which the use of bandages in the treatment of fractured tibia can be entirely dispensed with. The London Hospital, the New Marylebone Infirmary, the Royal Free Hospital, and the Westminster Hospital show beds which are of interest, but which contain no special novelties; and St. George's Hospital also exhibits some apparatus, but of a rather antiquated type.

Lastly, we may notice the bed shown by the hospitals of the army and navy, which illustrates the first treatment of wounds and fractures, and is a marvel of ingenuity. Esmarch's triangular bandages are used throughout, and we would especially direct attention to the treatment of fractured thigh; a rifle forms a long outside splint, a waist-belt supplies the place of a body-bandage, triangular bandages fix the impromptu splint to the thigh and ankle, and a third bandage is used as a perineal band; the same bandages serve to fix two bayonets to the arms, where they act as excellent splints; and a wound of the hand is also dressed with this bandage. If any fault can be found, it must be with the tourniquet in use, which we have heard described by a good authority as the worst in existence.

CARYATIDES FROM CADAVERA.

THE *British Medical Journal* is responsible for the reproduction of the following:—

A new method of inhumation has, according to the *Cronica Medica Quirurgica Horana*, lately been recommended by an engineer, named Cruz. It is a procedure by which the bodies of the dead are incrustated in an artificial stone, which is perfectly impermeable to gases, and which consequently will not permit the escape of the slightest mephitic emanations. Before proceeding to the operation in question, the cadavera are submitted to the following treatment. The body is placed in a bath composed of equal parts of lime and clay, dissolved in a sufficient quantity of water. Upon the removal of the body, which is found to be covered with a thick layer of the above-named substance, it is covered with another layer of natural cement, destined to absorb the excess of water, after which the cadaver is submerged in a bath of pitch, and covered, finally, with a layer of lime: the contact, only, between the lime and the calcareous cement being sufficient to solidify the pitch rapidly, a thick coating being formed in this manner, which possesses the

same properties as the pitch of Judea, a substance to which the Egyptian mummies owe their peculiar indestructibility. As can be readily understood, a subject so prepared can exhale no marked odor; the different layers of lime, clay, and pitch forming around it a kind of solid wrapping, which is opposed, effectually, to the disengagement of gases. A cadaver, after being treated in this manner, is deposited in the interior of a

mould, which is filled with the following mixture, that very soon solidifies, and is transformed into stone: Cement, five parts; sand, three parts; ashes, two parts; water, a sufficiency. The stones which are obtained by this process acquire a remarkable solidity. Obituary inscriptions can be engraved upon them; they can be placed in mausolea, or may serve for the construction of sepulchral monuments of various forms.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 30, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2696 (no report from New York); 1380 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1015, diarrhoeal diseases 746, consumption 280, lung diseases 102, diphtheria and croup 97, malarial fevers 42, typhoid fever 40, scarlet fever 31, small-pox 27, measles 23, whooping-cough 19, cerebro-spinal meningitis 18, puerperal fever eight, erysipelas four. In addition, Nashville reports deaths from diarrhoeal diseases eight, consumption four, measles, typhoid fever, malarial fever, and puerperal fever one each, — total deaths and deaths under five years not given. From *typhoid fever*, Philadelphia 11, Chicago five, St. Louis, District of Columbia, and Pittsburgh three, Boston, New Orleans, and Charleston two, Brooklyn, Cincinnati, Milwaukee, Providence, Lowell, Fall River, Lynn, Holyoke, and Chelsea one. From *scarlet fever*, Pittsburgh seven, Brooklyn six, Philadelphia five, Buffalo four, Chicago and Milwaukee two, Baltimore, Cincinnati, Providence, Springfield, and New Bedford one. From *small-pox*, Philadelphia and Chicago 12, Pittsburgh three. From *measles*, Chicago seven, Brooklyn six, Baltimore three, Boston, Cincinnati, Pittsburgh, Buffalo, Milwaukee, Providence, and Fall River one. From *whooping-cough*, Philadelphia four, Baltimore and Cincinnati three, Brooklyn, Chicago, St. Louis,

and Buffalo two, Gloucester one. From *cerebro-spinal meningitis*, Chicago and St. Louis four, Lynn two, Baltimore, Cincinnati, Pittsburgh, Buffalo, Milwaukee, Fall River, Haverhill, and Brockton one. From *puerperal fever*, Chicago two, Brooklyn, Boston, St. Louis, Baltimore, New Orleans, and Attleborough one. From *erysipelas*, Philadelphia, St. Louis, New Orleans, and Weymouth one. Three deaths from sunstroke occurred in Cincinnati.

Eight cases of small-pox were reported in Brooklyn, 48 in Chicago, 40 in Pittsburgh, and one in Milwaukee; diphtheria 23, scarlet fever four, in Boston; scarlet fever 13, diphtheria five, in Milwaukee.

In 44 cities and towns of Massachusetts, with a population of 1,082,428 (population of the State 1,783,086), the total death-rate for the week was 23.12 against 22.56, and 20.07 for the previous two weeks.

For the week ending July 9th in 149 German cities and towns, with an estimated population of 7,789,743, the death-rate was 29.8. Deaths reported 4467; under five 2680: pulmonary consumption 485, diarrhoeal diseases 374, acute diseases of the respiratory organs 263, diphtheria and croup 114, scarlet fever 74, typhoid fever 44, whooping-cough 42, measles and röteln 41, puerperal fever 12, typhus fever (Königsberg two, Stettin two, Thorn three, Erfurt, Leipzig) nine, small-pox (Kö-

nigsberg two, Danzig, Berlin, Kottberg, Aachen) six. The death-rates ranged from 12.9 in Munster to 58.8 in Posen; Königsberg 35.1; Breslau 42.6; Munich 33.2; Dresden 26.1; Berlin 17.3; Leipzig 28.8; Hamburg 22.5; Hanover 17.4; Bremen 19.2; Cologne 25.5; Frankfurt 20.1; Strasburg 31.8.

For the week ending July 16th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 23.1. Deaths reported 3361: diarrhoea 414, acute diseases of the respiratory organs (London) 168, measles 115, scarlet fever 108, whooping-cough 96, small-pox (London 49) 52, fever 32, diphtheria 17. The death rates ranged from 14.7 in Bradford to

28.1 in Liverpool; Bristol 18.1; Sheffield 18.6; Birmingham 20.2; Manchester 22; London 24.7; Leeds 26; Liverpool 28.1. In Edinburgh 17.1; Glasgow 19.9; Dublin 21.1.

In the 21 chief towns of Switzerland, for the week ending July 16th, population 479,934, there were 31 deaths from diarrhoeal diseases, acute diseases of the respiratory organs 20, typhoid fever seven, diphtheria and croup six, whooping-cough five, measles two.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.		Thermom-eter.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 30, 1881, TO AUGUST 5, 1881.

KING, WILLIAM H., captain and assistant surgeon. Now awaiting orders at Greenacastle, Pa., to report in person to commanding general, Department of the East, for assignment to temporary duty. S. O. 171, A. G. O., July 28, 1881.

GARDNER, EDWIN F., first lieutenant and assistant surgeon. Relieved from duty in Department of Dakota, to proceed to Eastport, Me., and on arrival there report by letter to the surgeon-general. S. O. 171, C. S., A. G. O.

BOOKS AND PAMPHLETS RECEIVED.—On the Value of Phosphorus as a Remedy for Loss of Nerve Power and Functional Disorders of the Nervous System induced by Overwork and the Exigencies of Modern Life. By Edmund A. Kirby, M. D. Philadelphia: Presley Blakiston. 1881.

The Mother's Guide in the Management and Feeding of Infants. By John M. Keating, M. D. Philadelphia: Henry C. Lea's Son & Co. 1881.

Landmarks, Medical and Surgical. By Luther Holden, assisted by James Shuter, F. R. C. S. Third Edition. Philadelphia: Presley Blakiston. 1881.

Clinical Lectures on the Diseases of Old Age. By J. M. Chace, M. D. Translated by Leigh H. Hunt, M. D. With additional Lectures by Alfred L. Loomis, M. D. New York: William Wood & Co. 1881.

Official List of Medical Officers and Acting Assistant Surgeons of the United States Marine Hospital Service, with their Stations July 1, 1881.

Curtwright Prize Essay. Observations with the Nymphetom-eter upon the Globular Compositions of the Blood and Milk. By Frederick P. Henry, M. D. Philadelphia: F. A. Davis, 1881.

On the Park Worms (or Flesh Worms). How to Detect them, and How to Avoid them, being a Popular Account of their History, Modes of Propagation, and Means of Destruction, intended for the use of Farmers, Butchers, Pork Dealers, and the Owners of Pigs. By John Pinn. Rochester: The Rausch & Loomis Printing Company. 1881.

On the Larynx, or Laryngeal Phthisis. A Paper read before the New-England Medical and Surgical Society. By C. C. Lamb, M. D.

Stenosis of the Larynx, with Fibrous Adhesive Bands of the True Vocal Cords, Tracheotomy, etc.

Some Remarks concerning the Value of the Galvano-Cautery in Treatment of Diseases and Growths of the Naso-Pharynx. By W. H. Daly, M. D. (Reprint.)

Glaucoma caused by Mental Worry, illustrated by the Report of a Case. By Leartus Connor, M. D. (Reprint.)

Wood's Library of Standard Medical Authors. Vols. III., IV., V., and VI. A Treatise on Diseases of the Joints. By Richard Barwell, F. R. C. S. Illustrated by numerous Engravings on Wood. Second Edition, revised and enlarged.

A Treatise on the Continued Fevers. By James C. Wilson, M. D. With an Introduction by J. M. Da Costa, M. D.

A Medical Formulary based on the United States and British Pharmacopœias. By Lawrence Johnson, M. D.

Clinical Lectures on the Diseases of Old Age. By J. M. Chace, M. D. Translated by Leigh H. Hunt, M. D. With Additional Lectures by Alfred L. Loomis, M. D.

Supplement to Ziemssen's Cyclopædia of the Practice of Medicine. Edited by George L. Peabody, M. D. New York: William Wood & Company. 1881.

The Question of Axillary or Scapular Support in the Treatment of Joint Diseases of the Lower Extremity. By A. B. Judson, M. D. (Reprint.)

The Remedial Properties of the Hot Springs, Arkansas. Also a brief Consideration of the Locality as a Resort for Pithical Invalids. By Charles H. Lothrop, M. D. (Pamphlet.)

An Essay on Anti-septic Surgery. Read by Appointment before the Luzerne County Medical Society. By George W. Guthrie, M. D. (Pamphlet.)

On Cancer, its Allies, and other Tumors, with special reference to their Medical and Surgical Treatment. By F. Albert Pirell, M. D., with Microscopical Illustrations. Philadelphia: Presley Blakiston. 1881.

Antiseptic Surgery. The Principles, Modes of Application, and Results of the Lister Dressing. By Dr. Just Lucas-Championnière, Surgeon to the Hôpital Tenon, etc. Translated from the second and completely revised edition, with the special sanction of the Author, and edited by Frederic Henry Gerrish, M. D., Surgeon to the Maine General Hospital. Portland: Loring, Shost, and Harmon. 1881.

The Compend of Anatomy, for Use in the Dissecting Room and in preparing for Examinations. By John B. Roberts, M. D. Philadelphia: C. C. Roberts & Co. 1881.

Programme of the International Medical Congress.

INTERNATIONAL MEDICAL CONGRESS,

1881.

OPENING ADDRESS.¹

BY THE PRESIDENT, SIR JAMES PAGET, BART.

It is not necessary to defend the meeting of an International Congress. Such meetings have become one of the general customs of our time, and have thus given evidence that they are generally approved. Let me rather suggest to you some thoughts as to the work which, being in Congress, we have to do, and the spirit in which it may best be done, so that the good effects of our meeting may last long after our parting.

In the largest view of our design, it may seem to be that of bringing together a multitude of various minds for the promotion and diffusion of knowledge in the whole science and art of medicine, in their widest range, in all their narrowest divisions, in all their manifold utilities. And this design, I cannot doubt, will be fulfilled; for, although the programme tells of selected subjects for discussion, and defines the order of our work, yet knowledge will be promoted in a much wider range in the meetings without order, which will be held every day and everywhere — meetings of men with all kinds of mental power and all forms of knowledge and of skill; every one ready alike to impart and to acquire knowledge.

It is safe to say that in the casual conversations of this coming week there will be a larger interchange and diffusion of information than in any equal time and space in the whole past history of medicine. And with this interchange will be a larger increase, for in the mart of knowledge he that receives gains, and he that gives retains, and none suffer loss.

The increase will be the greater because of the great variety of minds which will meet. As I look round this hall, my admiration is moved not only by the number and total power of the minds which are here, but by their diversity; a diversity in which I believe they fairly represent the whole of those who are engaged in the cultivation of our science. For here are minds representing the distinctive characters of all the most gifted and most educated nations; characters still distinctly national, in spite of the constantly increasing intercourse of the nations. And from many of these nations we have both elder and younger men; thoughtful men and practical; men of fact and men of imagination; some confident, some skeptic; various, also, in education, in purpose and mode of study, in disposition and in power. And scarcely less various are the places and all the circumstances in which those who are here have collected and have been using their knowledge. For I think that our calling is preëminent in its range of opportunities for scientific study. It is not only that the pure science of human life may match with the largest of the natural sciences in the complexity of its subject-matter; not only that the living human body is, in both its material and its indwelling forces, the most complex thing yet known; but that in our practical duties this most complex thing is presented to us in an almost infinite multiformity. For in practice we are occupied, not with a type and pattern of the human nature, but with all its varieties in all classes of men, of every age and every occupation, in all climates and all social states; we

have to study men singly and in multitudes, in poverty and in wealth, in wise and unwise living, in health and all the varieties of disease; and we have to learn, or at least to try to learn, the results of all these conditions of life while, in successive generations and in the mingling of families, they are heaped together, confused, and always changing. In every one of all these conditions man, in mind and body, must be studied by us; and every one of them offers some different problems for inquiry and solution. Whenever our duty or our scientific curiosity or, in happy combination, both, may lead us, there are the materials and there the opportunities for separate original research.

Now, from these various opportunities of study, men are here in Congress. Surely, whatever a multitude and diversity of minds can, in a few days, do for the promotion of knowledge, may be done here. Every one has something he may teach, much more that he may learn; and, in the midst of an apparent utter confusion, knowledge will increase and multiply. It has been said, indeed, that truth is more likely to emerge from error than from confusion and, in some instances, this is true; but much of what we call confusion is only the order of nature not yet discerned; and so it may be here. Certainly, it is from what seems like the confusion of successive meetings such as this that that kind of truth emerges which is among the best moving and directing forces in the scientific as well as in the social life — the truth which is told in the steady growth of general opinion.

But it is not proposed to leave the work of the Congress to what would seem like chances and disorder, good as the result might be; nor yet to the personal influences by which we may all be made fitter for work, though these may be very potent. In the stir and controversy of meetings such as we shall have, there cannot fail to be useful emulation; by the examples that will appear of success in research, many will be moved to more enthusiasm, many to more keen study of the truth; our range of work will be made wider, and we shall gain that greater interest in each other's views and that clearer apprehension of them which are always attained by personal acquaintance and by memories of association in pleasure as well as in work. But as it will not be left to chance, so neither will sentiment have to fulfill the chief duties of the Congress.

Following the good example of our predecessors, certain subjects have been selected which will be chiefly, though not exclusively, discussed, and the discussions are to be in the sections into which we shall soon divide.

Of these subjects it would not be for me to speak even if I were competent to do so; unless I may say that they are so numerous and complete that — together with the opening addresses of the Presidents of Sections — they leave me nothing but such generalities as may seem commonplace. They have been selected, after the custom of former meetings, from the most stirring and practical questions of the day; they are those which most occupy men's minds, and on which there is at this time most reason to expect progress, or even a just decision, from very wide discussion. They will be discussed by those most learned in them, and in many instances by those who have spent months or years in studying them, and who now offer their work for criticism and judgment.

¹ Reprinted from advance sheets. Delivered August 3, 1881.

I will only observe that the subjects selected in every section involve questions in the solution of which all the varieties of mind and knowledge of which I have spoken may find their use. For there are questions, not only on many subjects, but in all stages of progress towards settlement. In some the chief need seems to be the collection of facts well observed by many persons. I say by many, not only because many facts are wanted, but because in all difficult research it is well that each apparent fact should be observed by many; for things are not what they appear to each one mind. In that which each man believes that he observes, there is something of himself; and for certainty, even on matters of fact, we often need the agreement of many minds, that the personal element of each may be counteracted. And much more is this necessary in the consideration of the many questions which are to be decided by discussing the several values of admitted facts and of probabilities, and of the conclusions drawn from them. For, on questions such as these minds of all kinds may be well employed. Here there will be occasion even for those which are not unconditionally praiseworthy, such as those that habitually doubt, and those to whom the invention of arguments is more pleasing than the mere search for truth. Nay, we may be able to observe the utility even of error. We may not, indeed, wish for a prevalence of errors; they are not more desirable than are the crime and misery which evoke charity. And yet in a Congress we may palliate them, for we may see how, as we may often read in history, errors, like doubts and contrary pleadings, serve to bring out the truth, to make it express itself in clearest terms and show its whole strength and value. Adversity is an excellent school for truth as well as for virtue.

But that which I would chiefly note, in relation to the great variety of minds which are here, is that it is characteristic of that mental pliancy and readiness for variation which is essential to all scientific progress, and which a great International Congress may illustrate and promote. In all the subjects for discussion we look for the attainment of some novelty and change in knowledge or belief; and after every such change there must ensue a change in some of the conditions of thinking and of working. Now for all these changes minds need to be pliant and quick to adjust themselves. For all progressive science there must be minds that are young whatever may be their age.

Just as the discovery of auscultation brought to us the necessity for a refined cultivation of the sense of hearing, which was before of only the same use in medicine as in the common business of life; or, as the employment of the numerical method in estimating the value of facts required that minds should be able to record and think in ways previously unused; or, as the acceptance of the doctrine of evolution has changed the course of thinking in whole departments of science, so is it, in less measure, in every less advance of knowledge. All such advances change the circumstances of the mental life, and minds that cannot or will not adjust themselves become less useful, or must, at least, modify their manner of utility. They may continue to be the best defenders of what is true; they may strengthen and expand the truth, and may apply it in practice with all the advantages of experience; they may thus secure the possessions of science and use them well, but they will not increase them.

It is with minds as with living bodies. One of their

chief powers is in their self-adjustment to the varying conditions in which they have to live. Generally those species are the strongest and most abiding that can thrive in the widest range of climate and of food. And of all the races of men they are the mightiest and most noble who are, or by self-adjustment can become, most fit for all the new conditions of existence in which by various changes they may be placed. These are they who prosper in great changes of their social state; who, in successive generations, grow stronger by the production of a population so various that some are fitted to each of all the conditions of material and mode of life which they can discover or invent. These are most prosperous in the highest civilization; these whom nature adapts to the products of their own arts.

Or, among other groups, the mightiest are those who are strong alike on land and sea; who can explore and colonize, and in every climate can replenish the earth and subdue it; and this not by tenacity or mere robustness, but rather by pliancy and the production of varieties fit to abide and increase in all the various conditions of the world around.

Now, it is by no distant analogy that we trace the likeness between these in their successful contests with the material conditions of life and those who are to succeed in the intellectual strife with the difficulties of science and of art. There must be minds which in variety may match with all the varieties of the subject-matters and minds which, at once or in swift succession, can be adjusted to all the increasing and changing modes of thought and work.

Such are the minds we need; or, rather, such are the minds we have; and these in great meetings prove and augment their worth. Happily the natural increase in the variety of minds in all cultivated races is — whether as cause or as consequence — nearly proportionate to the increasing variety of knowledge. And it has become proverbial, and is nearly true in science and art, as it is in commerce and in national life, that, whatever work is to be done, men are found or soon produced who are exactly fit to do it.

But it need not be denied that, in the possession of this first and chiefest power for the increase of knowledge, there is a source of weakness. In works done by dissimilar and independent minds, dispersed in different fields of study, or only gathered into self-assorted groups, there is apt to be discord and great waste of power. There is, therefore, need that the workers should from time to time be brought to some consent and unity of purpose; that they should have opportunity for conference and mutual criticism, for mutual help and the tests of free discussion. This it is which, on the largest scale and most effectually, our Congress may achieve; not, indeed, by striving after a useless and happily impossible uniformity of mind or method, but by diminishing the lesser evil of waste and discord which is attached to the far greater good of diversity and independence. Now, as in numbers and variety the Congress may represent the whole multitude of workers everywhere dispersed, so in its gathering and concord it may represent a common consent that, though we may be far apart and different yet our work is and shall be essentially one; in all its parts mutually dependent, mutually helpful, in no part complete or self-sufficient. We may thus declare that as we who are many are met to be members of one body, so our work for science shall be one though manifold; that as we, who are of many nations, will, for a time, for-

get our nationalities, and will even repress our patriotism, unless for the promotion of a friendly rivalry, so will we in our work, whether here and now or everywhere and always, have one end and one design,—the promotion of the whole science and whole art of healing.

It may seem to be a denial of this declaration of unity that after this general meeting we shall separate into sections more numerous than in any former Congress. Let me speak of these sections to defend them; for some maintain that even in such a division of studies as these may encourage, there is a mischievous dispersion of forces. The science of medicine, which used to be praised as one and indivisible, is broken up, they say, among specialists, who work in conflict rather than in concert, and with mutual distrust more than mutual help.

But let it be observed that the sections which we have instituted are only some of those which are already recognized in many countries, in separate societies, each of which has its own place and rules of self-government and its own literature. And the division has taken place naturally in the course of events which could not be hindered. For the partial separation of medicine, first from the other natural sciences, and now into sections of its own, has been due to the increase of knowledge being far greater than the increase of individual mental power.

I do not doubt that the average mental power constantly increases in the successive generations of all well-trained peoples, but it does not increase so fast as knowledge does, and thus, in every science, as well as in our own, a small portion of the whole sum of knowledge has become as much as even a large mind can hold and duly cultivate. Many of us must, for practical life, have a fair acquaintance with many parts of our science, but none can hold it all; and for complete knowledge, or for research, or for safely thinking out beyond what is known, no one can hope for success unless by limiting himself within the few divisions of the science for which, by nature or by education, he is best fitted. Thus our divisions into sections is only an instance of that division of labor which, in every prosperous nation, we see in every field of active life, and which is always justified by more work better done.

Moreover, it cannot be said that in any of our sections there is not enough for a full strong mind to do. If any one will doubt this, let him try his own strength in the discussions of several of them.

In truth, the fault of specialism is not in narrowness, but in the shallowness and the belief in self-sufficiency with which it is apt to be associated. If the field of any specialty in science be narrow, it can be dug deeply. In science, as in mining, a very narrow shaft, if only it be carried deep enough, may reach the richest stores of wealth and find use for all the appliances of scientific art. Not in medicine alone, but in every department of knowledge, some of the grandest results of research and of learning, broad and deep, are to be found in monographs on subjects that, to the common mind, seemed small and trivial.

And study in a Congress such as this may be a useful remedy for self-sufficiency. Here every group may find a rare occasion, not only for an opportune assertion of the supreme excellence of its own range and mode of study, but for the observation of the work of every other. Each section may show that its own

facts must be deemed sure, and that by them every suggestion from without must be tested; but each may learn to doubt every inference of its own which is not consistent with the facts or reasonable beliefs of others; each may observe how much there is in the knowledge of others which should be mingled with its own; and the sum of all may be the wholesome conviction of all that we cannot justly estimate the value of a doctrine in one part of our science till it has been tried in many or in all.

We were taught this in our schools; and many of us have taught that all the parts of medical science are necessary to the education of the complete practitioner. In the independence of later life, some of us seem too ready to believe that the parts we severally choose may be self-sufficient, and that what others are learning cannot much concern us. A fair study of the whole work of the Congress may convince of the fallacy of this belief. We may see that the test of truth in every part must be in the patient and impartial trial of its adjustment with what is true in every other. All perfect organizations bear this test; all parts of the whole body of scientific truth should be tried by it.

Moreover, I would not, from a scientific point of view, admit any estimate of the comparative importance of the several divisions of our science, however widely they may differ in their present utilities. And this I would think right, not only because my office as president binds me to a strict impartiality and to the claim of freedom of research for all, but because we are very imperfect judges of the whole value of any knowledge, or even of single facts. For every fact in science, wherever gathered, has not only a present value, which we may be able to estimate, but a living and germinal power of which none can guess the issue.

It would be difficult to think of anything that seemed less likely to acquire practical utility than those researches of the few naturalists who, from Leeuwenhoeck to Ehrenberg, studied the most minute of living things, the Vibrionidæ. Men boasting themselves as practical might ask, "What good can come of it?" Time and scientific industry have answered, "This good: those researches have given a more true form to one of the most important practical doctrines of organic chemistry; they have introduced a great beneficial change in the most practical part of surgery; they are leading to one as great in the practice of medicine; they concern the highest interests of agriculture, and their power is not yet exhausted."

And as practical men were, in this instance, incompetent judges of the value of scientific facts, so were men of science at fault when they missed the discovery of anesthetics. Year after year the influences of laughing gas and of ether were shown: the one fell to the level of the wonders displayed by itinerant lecturers, students made fun with the other; they were the merest practical men, men looking for nothing but what might be straightway useful, who made the great discovery which has borne fruit not only in the mitigation of suffering, but in a wide range of physiological science.

The history of science has many similar facts, and they may teach that any man will be both wise and dutiful if he will patiently and thoughtfully do the best he can in the field of work in which, whether by choice or chance, his lot is cast. There let him, at least, search for truth, reflect on it, and record it accurately;

let him imitate that accuracy and completeness of which I think we may boast that we have, in the descriptions of the human body, the highest instance yet attained in any branch of knowledge. Truth so recorded cannot remain barren.

In thus speaking of the value of careful observation and records of facts, I seem to be in agreement with the officers of all the sections: for, without any intended consent, they have all proposed such subjects for discussion as can be decided only by well-collected facts and fair direct inductions from them. There are no questions on theories or mere doctrine. This, I am sure, may be ascribed, not to any disregard of the value of good reasoning or of reasonable hypotheses, but partly to the just belief that such things are ill-suited for discussion in large meetings, and partly to the fact that we have no great opponent schools, no great parties named after leaders or leading doctrines about which we are in the habit of disputing. In every section the discussions are to be on definite questions, which, even if they be associated with theory or general doctrines, may yet be soon brought to the test of fact; there is to be no use of doctrinal touchstones.

I am speaking of no science but our own. I do not doubt that in others there is advantage in dogma, or in the guidance of a central organizing power, or in divisions and conflicting parties. But in the medical sciences I believe that the existence of parties founded on dominant theories has always been injurious; a sign of satisfaction with plausible errors, or with knowledge which was even for the time imperfect. Such parties used to exist, and the personal histories of their leaders are some of the most attractive parts of the history of medicine: but, although in some instances an enthusiasm for the master-mind may have stirred a few men to unusual industry, yet very soon the disciples seem to have been fascinated by the distinctive doctrine, content to bear its name, and to cease from active scientific work. The dominance of doctrine has promoted the habit of inference, and repressed that of careful observation and induction. It has encouraged that fallacy to which we are all too prone, that we have at length reached an elevated sure position on which we may rest, and only think and guide. In this way specialism in doctrine or in method of study has hindered the progress of science more than the specialism which has attached itself to the study of one organ or of one method of practice. This kind of specialism may enslave inferior minds: the specialism of doctrine can enchain into mere dreaming those that should be strong and alert in the work of free research.

I speak the more earnestly of this because it may be said, if our Congress be representative, as it surely is, may we not legislate? May we not declare some general doctrines which may be used as tests and as guides for future study? We had better not.

The best work of our International Congress is in the clearing and strengthening of the knowledge of realities; in bringing, year after year, all its force of numbers and varieties of minds to press forward the demonstration and diffusion of truth as nearly to completion as may from year to year be possible. Thus, yearly, our Congress may maintain and invigorate the life of our science. And the progress of science must be as that of life. It sounds well to speak of the temple of science and of building and crowning the edifice, but the body of science is not as any dead thing of human work, however beautiful; it is a something liv-

ing, capable of development and a better growth in every part. For as in all life the attainment of the highest condition is only possible through the timely passing-by of the less good, that it may be replaced by the better, so is it in science. As time passes, that which seemed true and was very good becomes relatively imperfect truth, and the truth more nearly perfect takes its place.

We may read the history of the progress of truth in science as a paleontology. Many things which, as we look far back, appear, like errors, monstrous and uncouth creatures, were, in their time, good and useful, as good as possible. They were the lower and less perfect forms of truth which, amid the floods and stifling atmospheres of error, still survived; and just as each successive condition of the organic world was necessary to the evolution of the next following higher state, so from these were slowly evolved the better forms of truth which we now hold.

This thought of the likeness between the progress of scientific truth and the history of organic life may give us all the better courage in a work which we cannot hope to complete, and in which we see continual and sometimes disheartening change. It is, at least, full of comfort to those of us who are growing old. We that can read in memory the history of half a century might look back with shame and deep regret at the imperfections of our early knowledge if we might not be sure that we held, and sometimes helped onward, the best things that were in their time possible, and that they were necessary steps to the better present, even as the present is to the still better future. Yes, to the far better future; for there is no course of nature more certain than is the upward progress of science. We may seem to move in circles, but they are the circles of a constantly ascending spiral; we may seem to sway from side to side, but it is only as on a steep ascent which must be climbed in zigzag.

What may be the knowledge of the future none can guess. If we could conceive a limit to the total sum of mental power which will be possessed by future multitudes of well-instructed men, yet could we not conceive a limit to the discovery of the properties of materials which they will bend to their service. We may find the limit of the power of our unaided limbs and senses; but we cannot guess at a limit to the means by which they may be assisted, or to the invention of instruments which will become only a little more separate from our mental selves than are the outer sense-organs with which we are constructed.

In the certainty of this progress the great question for us is, What shall we contribute to it? It will not be easy to match the recent past. The advance of medical knowledge within one's memory is amazing whether reckoned in the wonders of the science not yet applied, or in practical results in the general lengthening of life, or, which is still better, in the prevention and decrease of pain and misery, and in the increase of working power. I cannot count or recount all that in this time has been done; and I suppose there are very few, if any, who can justly tell whether the progress of medicine has been equal to that of any other great branch of knowledge during the same time. I believe it has been; I know that the same rate of progress cannot be maintained without the constant and wise work of thousands of good intellects; and the mere maintenance of the same rate is not enough, for the rate of the progress of science should constant

ly increase. That in the last fifty years was at least twice as great as that in the previous fifty. What will it be in the next, or, for a more useful question, What shall we contribute to it?

I have no right to prescribe for more than this week. In this let us do heartily the proper work of the Congress, teaching, learning, discussing, looking for new lines for research, planning for mutual help, forming new friendships. It will be hard work if we will do it well; but we have not met for mere amusement or for recreation, though for that I hope you will find provision, and enjoy it the better for the work preceding it.

And when we part let us hear away with us, not only much more knowledge than we came with, but some of the lessons for our conduct in the future which we may learn in reflecting the work of our Congress.

In the number and intensity of the questions brought before us we may see something of our responsibility. If we could gather into thought the amounts of misery or happiness, of helplessness, or of power for work, which may depend on the answers to all the questions that will come before us, this might be a measure of our responsibility. But we cannot count it; let us imagine it; we cannot even in imagination exaggerate it. Let us hear it always in our mind, and remind ourselves that our responsibility will constantly increase. For, as men become in the best sense better educated, and the influence of scientific knowledge on their moral and social state increases, so, among all sciences there is none of which the influence and, therefore, the responsibility will increase more than ours, because none more intimately concerns man's happiness and working power.

But, more clearly in the recollections of the Congress, we may be reminded that in our science there may be, or, rather, there really is, a complete community of interest among men of all nations. On all the questions before us we can differ, discuss, dispute, and stand in earnest rivalry; but all consistently with friendship, all with readiness to wait patiently till more knowledge shall decide which is in the right. Let us resolutely hold to this when we are apart; let our internationality be a clear abiding sentiment, to be, as now, declared and celebrated at appointed times, but never to be forgotten; we may, perhaps, help to gain a new honor for science, if we thus suggest that in many more things, if they were as deeply and dispassionately studied, there might be found the same complete identity of international interests as in ours.

And then, let us always remind ourselves of the nobility of our calling. I dare to claim for it that among all the sciences ours, in the pursuit and use of truth, offers the most complete and constant union of those three qualities which have the greatest charm for pure and active minds, — novelty, utility, and charity. These three, which are sometimes in so lamentable disunion, as in the attractions of novelty without either utility or charity, are in our researches so combined that, unless by force or willful wrong, they hardly can be put asunder. And each of them is admirable in its kind. For in every search for truth we cannot only exercise curiosity, and have the delight — the really elemental happiness — of watching the unveiling of a mystery, but, on the way to truth, if we look well round us, we shall see that we are passing among wonders more than the eye or mind can fully apprehend. And as one of the perfections of nature is that in all her works

wonder is harmonized with utility, so is it with our science. In every truth attained there is utility either at hand or among the certainties of the future. And this utility is not selfish; it is not in any degree correlative with money-making; it may generally be estimated in the welfare of others better than in our own. Some of us may, indeed, make money and grow rich; but many of those that minister even to the follies and vices of mankind can make much more money than we. In all things costly and vainglorious they would far surpass us if we would compete with them. We had better not compete where wealth is the highest evidence of success; we can compete with the world in the nobler ambition of being counted among the learned and the good who strive to make the future better and happier than the past. And to this we shall attain if we will remind ourselves that as in every pursuit of knowledge there is the charm of novelty, and in every attainment of truth utility, so in every use of it there may be charity. I do not mean the charity which is in hospitals or in the service of the poor, great as is the privilege of our calling in that we may be its chief ministers, but that wider charity which is practiced in a constant sympathy and gentleness, in patience and self-devotion. And it is surely fair to hold that, as in every search for knowledge we may strengthen our intellectual power, so in every practical employment of it we may, if we will, improve our moral nature; we may obey the whole law of Christian love, we may illustrate the highest induction of scientific philanthropy.

Let us, then, resolve to devote ourselves to the promotion of the whole science, art, and charity of medicine. Let this resolve be to us as a vow of brotherhood; and may God help us in our work.

INTRODUCTORY REMARKS.

DELIVERED UPON THE OPENING OF THE SECTION ON
PATHOLOGY.

BY SAMUEL WILKS, M. D., F. R. S.

I welcome all of you here to-day. But are we not already of one brotherhood? Has not a common bond long ago united us in one family? Although we may not have shaken hands, we have been joined in spirit, or perhaps some of us have even been in more direct communication by means of winged words. Amongst all the ties which link man and man together, some of the closest are those forged by science. A special scientific inquiry will find two minds closely akin, although separated by thousands of miles, nationalities, or tongues. In our own department of pathology it creates a thrill of satisfaction to feel that the study of some morbid process may have led some of us to the discovery that another investigator, of whose existence we had been hitherto ignorant, has his thoughts and occupation in perfect unison with our own, and that although oceans and continents may separate us, our minds are both attuned to the same string. It is not surprising that the vast subject which more immediately occupies us can never cease to interest man in all its details, whilst he has a resting-place on this globe.

I would fain have inaugurated this Section with a general address, but have refrained from doing so, daring not to sacrifice to platitude our too precious time when so much practical work has to be accomplished.

I cannot, however, but occupy you a few moments

in order to take a glance at the immensity of the subject before us, embracing questions as it does in which humanity will be forever interested, namely, those referring to disease, decay, and death.

Our subject, in a word, is Pathology. Pathology has received various definitions, the most common being that which contrasts it with Physiology; for as the latter is regarded as the science of healthy organic life, so the former has been held to be the science of the unhealthy or of the abnormal course of life contrasted with the normal. This division of vital action into normal and abnormal is true in a superficial sense, and might be made theoretically to stand as a definition, but it is by no means applicable to our practical science of pathology, nor can it be made of any value as an expression of diagnostic knowledge in treating the thousand ills to which flesh is heir.

In the first place, it must be admitted that the changes which occur in every organic structure, as years roll on, are to be regarded as normal, unless we take an imaginary or ideal standard of a being living in some former golden age, where nought was known but perpetual youth, and regard every departure from this as morbid. Although we do not frame such a picture to ourselves, but know that the various changes in the bones, the cartilages, the lungs, the brain, and other parts which take place in age are in harmony with the dictates of Nature, yet how often are we called upon to treat these changes as forms of disease? They are, however, no more unnatural or pathological than the scere and yellow leaf which falls from the oak in autumn.

It, however, these senile changes occur prematurely, they will then be abnormal, and may be strictly regarded as morbid. Herein is one form of a pathological condition with which we have to deal—a premature decay arising from the various causes which bring the organism to an end, either from their operating with unusual force or from some inherent weakness in the body, which is unable to moderate their action. Now, if all these potent influences, instead of driving the mechanism too quickly, and so bringing it prematurely to an end, concentrate their forces upon one organ only, that organ would become, in ordinary parlance, diseased; but the process there set up may be of exactly the same nature as time would otherwise have produced. In comparatively young persons, for instance, we meet with fibroid and fatty changes in the heart and vessels, distention of the air-cells, alterations in the structure of bones and joints, which resemble in every respect those which age would have ordinarily induced. Therefore many of the conditions which we call disease seem nothing more than the result of the concentration on a particular organ of all those agencies which, under ordinary circumstances, bring about senile changes. These changes, therefore, although *crise* in character, are abnormal, and therefore may be rightly regarded as pathological.

The pathologist, therefore, cannot but regard the body in the first place in its physiological relations with its surroundings, and mark the alterations which time produces. The physiologist is aware that the production of force must be accompanied by loss elsewhere, seeing that gain and loss are equal, and therefore, in observing organic life, he must regard the destructive processes as well as the formative. He sees as if peep upon changes continually going on in relation with the atmosphere in which all living bodies

are steeped. The burning of the fuel in oxygen supplies the forces necessary for living processes; we therefore, although alive, are constantly being consumed. During so many years the body is undergoing combustion, or, we might say, slow destruction, and this process occurs much more rapidly in some persons and in some animals than in others. Why one creature should live longer or burn out sooner than another is not clear; why, for example, should a dog be worn out in ten or twelve years, its limbs be stiff, its sight and hearing impaired, its intellect obtuse, and senile changes be discoverable in its brain and elsewhere, when a parrot may take a century for the production of the same destructive changes? Why tissues of the same composition should wear out in one animal after ten revolutions of the earth when it takes a hundred revolutions to destroy similar ones in another, is by no means apparent. In man, if the destructive and reproductive changes are normally counterbalanced, the ordinary duration of life is reached. If the balance be not kept, the destructive agencies may be in the ascendancy, and life be shortened. If any of the ordinary surroundings which are always exerting their influences upon us, as various kinds of air, food, moral and mental moods, be in any way noxious, they may in time tend to premature death; and if they should act in such a manner as to cause localized organic changes, we should style these changes disease. There can be little doubt that a large number of maladies in England, as gout, Bright's disease, etc., are induced by mere excesses or inequalities in a mode of life which is considered ordinarily correct. It ought to be one of our studies to consider the relations of the human race to the soil, and observe all the circumstances which centuries have induced to bring about this normal or healthy relation between them. We might then observe the effects of the concentration of some of the more untoward of the influences which ordinarily environ it, as well as inquire into the effects of transplantation into another country. It seems that all the usual surroundings of life in civilized society, acting in undue proportion or in a more determined manner, induce a very large number of the diseases which we are called upon to treat.

In considering all these agencies working for what we call evil, and leading to destruction, we must not overlook an opposing law—that of reparation. Not only do we observe a production of living force in necessary association with a dissolution of material, but an ever-existing tendency towards the remaking of the injured tissues. We can scarcely think of a morbid change in the body which is not attended by another which has an opposite tendency. Every phthisical lung showing destruction of the tissue exhibits at the same time the attempt to limit the process and to save life by shutting off the escape of air from the lung or sealing the ulcerated blood-vessels.

Then, again, in considering the definition of disease, after having observed how large a number of maladies are produced by the influences of all our ordinary surroundings, we have to recognize those external causes of an extraordinary or specific character which prey upon the human frame, and often bring its machinery to an end. Now, if these causes are obviously parasitic, we are not witnessing so much the case of disease as the spectacle of one animal preying upon another. As regards the parasite, it is pursuing its normal life history, and as regards the patient or the host, he is simply being destroyed; the difference in his mode of

death from that which would result from the onslaught of a wild animal would consist merely in time. If a man fall a victim to the bite of a cobra, he is not said to die of disease; but the term is applicable if he die of glanders. There is this difference, however, in the latter case—the poison is not a natural one even in the infecting animal. If, however, in these infectious diseases the morbid cause be an animal or vegetable organism, although microscopic, then we really have to deal with the operation of one living being acting upon another, and the so-called specific malady exhibits nothing more than the natural course of life of certain specific organisms. The term disease, according to the definition, is here again scarcely applicable.

All these abnormalities of the human organism, under whatever conditions they may arise, suggest that as every branch of biological science is being studied in relation to the lower organizations, and according to the law of evolution, so must pathology become the subject of a large field of inquiry, and be made to embrace the diseases of all animal and vegetable life. The comparison of disease in man and animals may throw much light upon its nature, and it is remarkable that so few persons have been stimulated to the work, by considering the long controversy which has taken place as to the relation between vaccinia and variola, or hydrophobia and rabies. A true human pathology should have its basis in comparative pathology. Here lies a mine of wealth but little worked. As at the present time every structure and function of the human body is being studied in reference to its antecedents in the lower animals, so there can be no doubt that the various morbid changes to which it is liable may be also profitably discussed in reference to similar actions in more simple forms of life. The truth of this has been clearly seen by philosophers who have had no special acquaintance with our department of science. Thus Buckle, in his *History of Civilization in England*, says: "The best Physiologists distinctly recognize that the basis of their science must include not only the animals below man, but also the entire vegetable kingdom, and that without this commanding survey of the whole realm of organic nature we cannot possibly understand even human physiology, still less general physiology. The Pathologists, on the other hand, are so much in arrear, that the diseases of the lower animals rarely form parts of their plan, while the diseases of plants are almost entirely neglected, although it is certain that until all these have been studied, and some steps taken to generalize them, every pathological condition will be eminently empirical on account of the narrowness of the field from which it is collected." This is almost as true now as when written, several years ago; but we are pleased to think that our countryman, Sir James Paget, has already removed this slur upon our scientific procedure by his lecture on "Elemental Pathology," in which he shows the importance of observing the resemblances between the changes in the various tissues of man and the vegetable world, and also the deductions to be drawn therefrom.

Again, if the specific diseases be due to organisms, and the hypothetical *contagium vivum* be a reality, it must be subject to the same laws as other organic matter; and if the doctrine of evolution be true, it must have numerous relations with families of its own kind, and perhaps with others which are now obsolete. This idea has occupied the minds of several medical

men in this country, and it will no doubt further fructify in their hands.¹

A highly contagious disease prevailing in a particular locality may be exhibiting the differentiation of some more simple, less virulent, and widely-spread disorder. For example, a slightly contagious epidemic sore-throat might in course of time develop into a more virulent one until it culminated in diphtheria; and if this disease be due to an organism, the latter might have found a more genial soil for its development, or be altered by propagation and time, so that new properties might at last have been added to it. There may be a progressive development of infectiveness. Then, again, the doctrine of natural selection might obtain in the fact of some specific diseases remaining amongst us, while others have become obsolete. The same law, too, if allowed its full operation, might tend still more than it does to the subjugation of many hereditary diseases; for as these appear in youth, and often cause death, they would fade away by a process of self-destruction. As regards the specific diseases, we see again how the most susceptible persons would be struck out by the poison and the least susceptible remain, so that the poison would be modified in its virulence. We witness this fact in the more moderate characters of the exanthemata in all civilized nations, in comparison with the more profound effects produced by them in nations where the diseases had been hitherto unknown, as, for example, the fatality in the Pacific Islands of our comparatively mild British measles.

Besides the maladies which are induced by the evil influences of our ordinary surroundings, and those due to specific causes just named, there is a class of diseases styled new growths, which take a very large share in adding to man's mortality. The advance made in our knowledge of these structures is very considerable, and is still rapidly progressing towards a determination of their origin and the discovery of their relation to the normal tissues. These investigations are assisting us in discarding some of our older notions regarding their constitutional and malignant nature, and proving that many are accidental in their origin, and therefore may possibly be averted.

In these brief remarks we see how the simple definition of pathology as a deviation from the healthy standard fails in its application, and how wide is the range of subjects included in its domain. What these are, you, gentlemen, are about to illustrate in the different subjects which you will bring before the section.

INTRODUCTORY ADDRESS.

BY THE PRESIDENT OF THE SECTION ON SURGERY,

JOHN ERICH ERICHSEN, F. R. S., ETC.

GENTLEMEN,—Surgery is never stationary. To be stationary while all around is in movement would be practically to retrograde. But movement does not necessarily mean advance. The general direction of the movement may undoubtedly be forwards, but the factors of that movement do not all equally tend to progress. When the history of surgery comes to be written,—and this has never yet been done,—it will be found that the surgery of the nineteenth century has not been uniform in its progress in all departments; that its advance has not been continuously in one line, but that its progress has been materially affected by the prevail-

¹ Dr. Airy, Dr. Thorne, etc.

ing bias of the professional mind of the day. Anatomical at one time, physiological at another, the tendency of the surgery of the present day is influenced in one direction by the mechanical spirit of the age, and in another by the advanced pathology which is one of its chief medical characteristics. Yet the continuous advance of our art is undoubted. The gain that thus results has been definitively secured to surgery and to mankind. It can never be lost. Every conquest that has been made has been permanent. Year after year some new position has been won, often, it is true, after a hot conflict of opinion; but once occupied it has never been abandoned. Thus our standpoint has ever been pushed on in advance. For knowledge in science is cumulative, and skill in art is a tradition that is hereditarily transmitted from master to pupil, if not by the individual, yet by the profession to which he belongs, from which he has acquired and to which he bequeaths it, augmented and perfected by his own labors. With the knowledge of our predecessors we are familiar; to its stores each generation has added. What they have done has been transmitted to us, and we can readily accomplish. In what we can do, we may be sure, our successors will not fail.

It is well that from time to time this advance should be measured, this gain weighed. The business of this section is not only to measure the extent of the advance, but to determine the value of the gain, and to do this, not so much by the novelty of the practice, or by the brilliancy of its exposition, as by an estimate of its intrinsic merit, as shown by its proved utility. Our business here has to do with practical considerations, having reference to the recent advances in, or the future lines to be followed by, modern surgery.

The executive of this section has proposed eight subjects for the consideration of its members. It is hoped that these will be found to include the more important surgical questions that are at present most prominently before the profession. The short time at our disposal, which will scarcely enable us to do full justice even to these subjects, has prevented the possibility of our bringing forward other and perhaps equally interesting questions; but some of these will be found to have received consideration in the papers which will be read, either *in extenso* or in abstract, as time may allow.

I will now briefly refer to the more important subjects that have been set down for our consideration.

(1.) In no department of surgery has a more marked or a more brilliant advance been made of late years than in that which concerns the operative treatment of intra-peritoneal tumors.

The establishment of ovariectomy as a recognized surgical operation has now long been matter of history, but the perfection of safety to which it has of late years been carried, by the improvement of its details, has led the way to a vast and rapid extension of operative surgery for the cure or relief of various diseased abdominal organs. The uterus and the spleen, the stomach, the pylorus and the colon, have each and all been subjected to the scalpel of the surgeon; with what success has yet to be determined; and it is for you to decide whether some, at least, of these operations constitute real and solid advances in our art, or whether they are rather to be regarded as bold and kingly experiments on the endurance and reparative power of the human frame—whether in fact they are crowned triumphs or operative audacities. They must, indeed, be a credit to the progress of operative surgery

in this direction. Are we at present in a position to define it? There cannot always be new fields for conquest by the knife; there must be portions of the human frame that will ever remain sacred from its intrusion, at least, in the hands of the surgeon. May there be not some reason to fear lest the very perfection to which ovariectomy has been carried may lead to an over-sanguine expectation of the value and the safety of the abdominal section, and exploration when applied to the diagnosis or cure of diseases of other and very dissimilar organs, in which but little of ultimate advantage, and certainly much of immediate peril, may be expected from operative interference?

(2.) In the discussion of the next great question, I would submit that we may, with advantage, direct our attention less to the mere mechanical—the simple operative part of the business, the details of which are now well understood—than to the consideration of those higher questions as to the diagnosis and nature of the various forms of renal disease, in which nephrotomy and nephrectomy may be respectively used, with a reasonable hope of relief or cure. And in considering the prospects afforded by these operations in the improvement of the health and the mitigation of the sufferings of the patient, it is surely not the least interesting point for us to study the after-physiological effects produced on the system by the extirpation of so important an eliminatory organ as the kidney.

(3.) We naturally pass from the consideration of operations on the kidney to that of those which implicate the bladder; and in doing so we have specially to direct our attention to the question as to what advances have of late been made in lithotomy and lithotripsy.

In lithotomy we see much of change, possibly something of novelty, but not so certainly anything of real progress. Have we indeed advanced one single step either in the perfection or in the results of that operation since the days of Cheselden, of Martineau, or of Crosse, not to mention the names of more recent but equally illustrious surgeons and successful operators? The revived median, the combination of it with lithotripsy, the suprapubic, whether done antiseptically or not, have certainly not been very encouraging in their results, and can scarcely claim to be considered in the light of an advance on the old lateral operation in skillful hands. But yet we must admit that these methods of lithotomy may deserve this consideration—that possibly, in some forms of calculus, and in certain conditions of the urinary organs, a wise eclecticism may be exercised in the choice of one or other of them.

In lithotripsy, however, it is probable that a great and real advance has been made, and certainly it is undoubted that a complete revolution has been effected by the enterprise and skill of one of our American brethren, for it cannot be questioned that "Bigelow's operation" has completely changed the aspect of lithotripsy, and there is every reason to believe that it constitutes one of those real advances in a method which marks an epoch not only in the history of the operation itself, but in the treatment of the disease to which it is applicable.

But here a fertile field opens up for our deliberation. We have to consider not only in what cases as regards the mere size of calculus, "Bigelow's operation" may safely be used; but also, and far more important than this, the ultimate result both upon the bladder and the kidney of prolonged intra-vesical instrumentation. The mere question as to the compar-

ative advantages of removal of stone by one or by several sittings, is dwarfed by the more important one of determining the state of the bladder that results, not perhaps so much as concerns the life as the future comfort of the patient. It is here that information is much needed, and it is here that unfortunately, but for very obvious reasons, the lithotritist himself may in many cases be unable to furnish it.

(4.) Pre-historic man was doubtless a victim of injury before he became the sufferer from disease, and the treatment of wounds constituted probably the first effort of the healing art. From the earliest dawn of human intelligence the attempt to cure a wound must have suggested itself to man, and yet at the close of the nineteenth century we are still discussing the best methods of doing this, and the causes of their failure. There is still difference of opinion and of practice amongst surgeons, not only as to the comparative advantages of the "open air" method, and that in which all atmospheric contact is carefully guarded against; of the "dry" and of the "moist" system of dressing; as to whether the "antiseptic method" in a modified form sutures, or whether the more elaborate system of local treatment before, during, and after an operation, which has been devised by the skill and worked out by the unwearied labor of Lister, be essential in all cases of operation wound. Not, of course, for its primary union—for this may be obtained by any and every of the methods mentioned. If it be contended that this system is necessary for the safety of the patient, and the due healing of the wound in some cases, has it been proved to be equally essential in traumatic lesions of all tissues, of all organs, and of all regions? These are questions that may well deserve the consideration of this section. But there are others of a yet wider character that must also engage our attention in any discussion on the best methods of securing primary union in wounds, for it is impossible to fail to recognize in the general constitutional state of the patient a most important factor in this direction; and we should be taking a narrow view of this many-sided question, if we did not give due weight to the influence of those hygienic conditions which, if faulty are inimical, or even destructive to, the due performance of those actions which are necessary for the maintenance of the organism in a healthy state, and for the proper nutrition and consequent repair of the tissues of the body. Is there no fear that in some of the modern systems of treating wounds we are in danger of expending all our precautions in the prevention of the local and of ignoring the risk of a constitutional infection?

(5.) The treatment of aneurism is one of those great questions which from an early period in the history of modern surgery has occupied the attention of practitioners, and has undergone no little fluctuation. A few years ago the battle between the ligature and compression appeared to have been decided in favor of the latter; but the invention of improved ligatures, made of various kinds of animal tissue, and applied with antiseptic precautions, has once more inclined the balance of professional opinion towards the Hunterian operation. But now again the practice of compression has received renewed strength from the employment of Esmarch's elastic bandage in the cure of certain forms of external aneurism, and it is for you to determine in what cases it can be used with advantage, and in what way a cure is effected by its means. For in the treatment of aneurisms, as in that of so many other

surgical diseases, the wiser and more scientific course is to follow a judicious system of selection in the method to be employed in each particular case, rather than to subject all to one unbending line of practice.

(6.) The treatment by re-section of some forms of chronic and otherwise incurable joint diseases, has in certain articulations, and at suitable ages, met with the universal approbation of surgeons, and the wide extension of the principles of "conservative surgery," is one of the most striking evidences of advance in our art in modern times. Re-section has, however, of late years come to be extensively applied to the treatment of cases of articular disease which formerly were subjected to procedures of a less heroic character; and it will be for the members of this section to weigh carefully the wisdom of such a measure, and to contrast its results, both as regards life of patient and after utility of limb, with those which may be obtained from the employment of milder means, such as absolute immobility with extension, and possibly, in some cases, simple incision of the articulation.

(7.) In considering the relations between adenoma, sarcoma, and carcinoma in the mammary gland of the female, I would venture to submit that this subject has to be discussed here from its clinical rather than from its pathological side. We have here less to do with the ultimate structure of the tumors, with their histological affinities, with the parts that are played by epiblasts and mesoblasts, with what epithelium or connective tissue cells can or cannot do, than with their clinical history, their differential diagnosis in their earlier stages, the best time for their removal by operation, the liability to recurrence after operation, and the possibility in recurrence of the substitution of one form of disease for another. With these, and such questions as these, we, as clinical surgeons, may advantageously occupy ourselves.

(8.) The last subject set down for discussion is one that has practical bearings of an importance that cannot be overestimated. There are few questions of the present day of deeper surgical or social interest than the far-reaching, the apparently illimitable, and most pernicious, extension of a syphilitic contamination of organs and of tissues; of the modifications impressed by it on other diseases that are the local developments of diatheses, whether strumous, tubercular, rheumatic, or gouty. Does the diathesis exercise any influence upon the form assumed by the syphilitic disease, and to what extent does it modify the characters presented by it in its primary and its secondary affections, more especially when the latter manifest themselves upon the skin or in the bones; how far are gummata and caries, psoriasis and rupia the consequences of a constitutional impress, influencing the direction of the syphilitic poison? To what extent may rickets and gray granulations be the ultimate products of the syphilitic taint? These and various other questions will probably occupy the attention of those who enter on the discussion of this wide-spreading subject.

We hope to be able to take the discussion of two questions on each day, so as to work through the eight in the time allotted to us. In addition to these there are various detached papers on subjects which are of much interest, but which scarcely admit of being classified under one or other of the above heads of discussion. These we shall take up as time and opportunity admit, but their number is so great that it is to be feared that full justice can scarcely be done to all, and

that it will be unavoidable, on account of the limited time at our disposal, that a large number be read in abstract.

OPENING ADDRESS IN THE SECTION ON OBSTETRICS.

BY ALFRED H. McLINTOCK, M. D., LL. D.,
President of the Section.

In opening the obstetric section of this Seventh International Medical Congress, the first and most gratifying duty that devolves upon your President is to offer an earnest and hearty welcome to those obstetric members who have come from other nationalities, and from distant British colonies, to take part in this, the largest convention of medical men that has ever, perhaps, assembled together at any one time or place.

I present this cordial salutation, not only on the part of the officers and council of the particular section over which I have the honor to preside, but also on the part of the obstetricians and gynecologists of England, Scotland, and Ireland.

We are proud and happy to meet here on British ground so many of our brethren from various parts of the civilized world, but especially from Germany, France, and America, and to accord them a friendly greeting, not only out of respect to their individual merits and high reputation, but as representing those great obstetric schools over which the names of Mauriceau, Levret, Baudelocque, and Dubois; of Roederer, Siebold, Naegele, Kiwisch, and Seanzoni; and of Bard, Dewees, Meigs, and Hodge, have severally shed such imperishable lustre!

Not the least of the important objects contemplated in this Congress is the interchange of friendly feelings among its members. I am fully persuaded that our reunions will be attended, not alone with benefit to us all by the attrition of mind with mind,—but that new friendships will be formed, and old friendships confirmed, and that sentiments of mutual respect and regard will be developed, so as to strengthen the bond of brotherhood which should unite us as fellow-workers in the same department of medicine.

Allow me, before going further, to express my deep sense of the unexpected, unmerited dignity which the Congress has conferred by putting me into the position of President of this important Section; I feel it to be the highest and most flattering honor of my long professional life. Such a compliment more than repays me for forty years of labor and devotion; for it sets the seal of approval by contemporaries on my past life, and leaves nothing further or higher to aspire to in the way of professional distinction. At the same time, gentlemen, this feeling of just pride and exaltation is mingled with a very poignant sense of incapacity, and I might well shrink from the responsibility of the post, but that in the discharge of its duties, I shall have the aid and cooperation of such accomplished men as those who constitute the Vice Presidents and Council of the section; they in truth are the giants on whose shoulders I am raised to the exalted position it is my good fortune to occupy in this Congress.

Inasmuch as this is the first occasion of the International Medical Congress meeting in London, it may not be inappropriate if I pass in review some of the more prominent among the many eminent obstetricians who lived and practiced in this city, who by their writings, teaching, and discoveries have contributed in no

small measure to the development of midwifery and gynecology, as well as to the medico-chirurgical fame of London.

I must, however, study brevity, being desirous, if possible, to keep within the fifteen minutes allowed for the readings of communications, so as to set an example of obedience to the rules of the Congress.

In this retrospective glance, I find only one name standing out in the sixteenth century, Thomas Raynald, the translator of Eucarius Rhodion's celebrated treatise, *De Partu Hominis*. The original English edition, by Raynald, appeared about 1540, and was the first distinct treatise on Midwifery in the English language, and for over a hundred years was the sole guide and text-book of obstetric practitioners, male and female.

In the early part of the seventeenth century, the immortal William Harvey (*tanto nomini nullum par enlogium*) stands forth conspicuous, the splendor of his fame increasing as years roll on. He spent most of his time here, being physician to the King; and he delivered courses of lectures, at the Royal College of Physicians, on anatomy and surgery. As a practitioner we know from the testimony of his contemporaries that Harvey excelled in midwifery, and in the treatment of female diseases.

Before the publication of his celebrated exercises on generation, parturition, conception, etc., there were, according to Dr. Aveling, "but three works on midwifery in our language; these were translations from Rhodion, Rueff, and Guillemeau. His was the first book on midwifery written by an Englishman, printed in our own language, and the influence which it had upon the practice of the time would with difficulty now be estimated. His claim therefore to eminence in our department of medicine is beyond question." With this conviction on our minds, we shall the more heartily yield our applause when his magnificent memorial statue is unveiled at Folkestone, the place of his nativity, on Saturday next,—a ceremony, I may remark, which has with good taste and judgment been purposely so arranged that this great Medical Congress may take a part in showing honor and respect to the memory of one of the greatest discoverers in the science of medicine, and, consequently, one of the greatest benefactors to the human race.

Contemporary with Harvey was another remarkable man, Peter Chamberlen, the inventor of the midwifery forceps, indisputably the most valuable instrument of the whole *armamentarium chirurgicum*. Unfortunately for him, however, the brilliancy of his reputation is obscured by the unworthy selfish conduct which caused him to keep the instrument a secret for the aggrandizement of himself and family. He was father of Dr. Hugh Chamberlen, the translator into English of Mauriceau's works. There is a handsome monument to the memory of this Dr. Hugh Chamberlen in Westminster Abbey, erected by his patron and friend, the Duke of Buckingham. No less than five generations of the Chamberlen family were eminent in the medical profession here; and Dr. Peter, who attained a great age, had been physician to five English sovereigns.

Towards the close of this (seventeenth) century, Richard Wiseman, "Serjeant Chirurgion" to Charles I., published his treatise on surgery, in which he gives an excellent description of pelvic abscesses, consequent on parturition. He thus anticipated Puzos' essay on the same disease, and put forward much more rational and correct views as to its pathology.

The eighteenth century was destined to see a marvellous development of midwifery, as well as of many other arts and sciences. As might therefore be expected, London can boast of several eminent obstetricians at this period.

In chronological order, the first to be mentioned is Dr. John Arbuthnot, F. R. S. and F. R. C. P., physician to Queen Anne. Although he has left no enduring evidence of obstetric superiority, yet he was an eminent accoucheur in his day, and reflected infinite credit on our order by his rare literary talents, his deep scholarship, and his exalted social position. He was skilled in everything that related to science, and held a prominent place among the ablest writers and wits of that Augustan age; one of whom (Swift or Pope) alludes in his poetry to

"Arbuthnot's soft obstetric hand."

A man who was considered a friend and an equal by Parnell, Gay, Bolingbroke, Swift, and Pope could not fail to adorn any pursuit to which he devoted his vast intellectual powers. Speaking of him, Swift said, "He has more wit than we all, and his humanity is equal to his wit." A higher tribute could not have been paid him.

The next to be mentioned is Dr. John Maubray, not on account of any peculiar merit in either of his works, — *The Female Physician*, and *Midwifery brought to Perfection*, — but because he is reputed to have been the first public teacher of midwifery in this country. He lectured, Dr. Denman tells us, at his house in Bond Street, so far back as the year 1724.

Nearly cotemporary with Maubray was Dr. Edmund Chapman. He was the second public teacher of midwifery in this city, and is entitled to our lasting gratitude for having been the first to publish to the world a description of that "noble instrument" (to use his own phrase), the obstetric forceps, the secret of which the Chamberlens kept to themselves for over fifty years. This he did in the *Edinburgh Medical Essays*, and subsequently in his treatise *On the Improvement of Midwifery chiefly with Regard to the Operation*: the operation meaning the application of the forceps. The first edition of this book came out in 1733.

About this same period also lived Sir Richard Manningham, F. R. S., a man of considerable learning and of great reputation as a successful midwifery practitioner. He was author of some obstetric works of temporary consequence, and his claim to remembrance arises from the circumstance that in the year 1739 he opened a ward in the Parochial Infirmary of St. James', Westminster, exclusively for the reception of parturient women, which was the first thing of the kind in Great Britain. Shortly afterwards the idea was taken up and enlarged upon elsewhere, and the great Lying-in Hospital of Dublin was founded by Dr. Bartholomew Morse, being the first hospital of the kind in the British Dominions.

The very same year that Sir Richard Manningham opened his obstetric ward in St. James's Infirmary, as we have just seen, a surgeon from a small country town in Scotland established himself here in London as an accoucheur, who ultimately effected the greatest reformation that had yet taken place in the principles and practice of obstetrics. This man was William Smellie, a name always to be respected wherever midwifery is cultivated as a science. For twenty years

Smellie practiced and taught here, and published the first volume of his celebrated treatise in 1751, and his splendid anatomical plates in 1754. Amongst his pupils who later on became eminent in the same branch of medicine were William Hunter, Denman, David McBride (of Dublin), John George Roederer (subsequently Professor of Midwifery at Göttingen), Dr. James Lloyd, of Boston, U. S., and Dr. William Shippen, afterwards Professor of Midwifery in the Pennsylvania University; these last being, according to Professor Parvin, "the two first American obstetric practitioners." Most gladly would I linger over the life and works of this great man, but I must content myself with a few sentences.

Smellie possessed a wonderful capacity for work, and a clear judgment; but beyond and above this he was endowed with a singularly accurate perception of facts, which made him as well as a close observer of nature. Herein lay the secret of his unrivaled success as a reformer and improver of midwifery. He himself felt this to be so, for in reviewing his practice, he says, "I diligently attended to the course and operations of nature which occurred in my practice, regulating and improving myself by that infallible standard." (Case 186, Sydenham Society Edition.) Truly, he was, in the words of Dr. Hugh Miller, a "noble character and an example of earnest living."

A couple of years after Smellie settled in London, there came to live with him a young man from the Scottish county — Lanarkshire — of which Smellie himself was a native. This young man was no less a person than William Hunter — a name familiar to you all — whose plates and descriptions of the human gravid uterus have gained their author a foremost rank among obstetric writers. By his great reputation as a lecturer and as an anatomist, aided no doubt by his prepossessing appearance, polished manners, and cultivated mind, Hunter proved a successful competitor of Smellie's in practice. Like him, he also gave special courses of lectures on midwifery, MS. notes of which are to be found in many libraries. Dr. Matthews Duncan tells us the College of Physicians possesses two pretty complete volumes of such notes.

In 1748, Hunter was appointed surgeon and man-midwife to Middlesex Hospital, and soon afterwards to the British Lying-in Hospital; for though the Physicians claim him as belonging to themselves, yet it cannot be disputed that Hunter was a surgeon, and a member of the Corporation of Surgeons of this city.

Besides being a rival, he was in some respects a contrast to Smellie. The school of obstetrics founded by the latter was not inaptly described by the late Tyler Smith as the mechanical school, from the importance it attached to the resources of art in aiding parturition. Hunter, on the other hand, placed extraordinary reliance on the powers of nature, and trusted too much to tincture of time. Hence his followers have been designated the physiological school; and through the influence of his commanding authority, they formed a large section of the profession, and could boast some great names.

Although we may regard Hunter as one of ourselves, and appropriate much of the glory with which his name is invested, yet it is necessary (as Dr. Duncan observes) with a view to justice to point out that his obstetrical fame is chiefly anatomical, and that his greatest claim on our admiration and gratitude arises

from his anatomical work and influence." (Harveian Address, 1876.)

It is a just boast of the English school of midwifery that what, in the truest and strictest sense, is "the most conservative of all the resources of our art," was first formally admitted a place among obstetric operations, in this city and about the year 1756. The recognition by the profession of the artificial induction of premature labor was the outcome of a medical conference held at the time and place just mentioned. Who was the first or most strenuous advocate of the operation at that conference does not appear; but we do know that the first to put it in practice was Dr. Macaulay, a midwifery practitioner of this city. It is natural and just, therefore, to identify his name with this most beneficent measure, and to accord him a prominent place among the many distinguished accoucheurs who lived and practiced here.

One of the greatest ornaments of that physiological school of accoucheurs — founded we may say by William Hunter — was Thomas Denman, a man of remarkably sound judgment, great prudence, and of the highest moral integrity. Throughout half a century he lectured and practiced in this city. His work, entitled *An Introduction to the Practice of Midwifery*, is well known to most of you. It has many peculiar excellencies, but to my mind the chief is his classification of labor, which is at once comprehensive, pathological, and practical, and thereby serves the highest purposes of any system of classification.

Did time permit, I could multiply these brief sketches so as to include many other London obstetricians who lived since the commencement of the present century, of less note, it is true, but yet men who stood far above mediocrity, and who, by their writings, their teaching, and their practice, materially aided the advancement of midwifery and gynaecology. I must content myself, however, with a mere recital of their honored names, namely: John Clarke, Orborne, Leake, Bland, Merriam, Charles Clarke, Gooch, David Davis, Blundel, John Ramsbotham, Marshal Hall, Robert Lee, Robert Ferguson, Rigby, jun., Francis Ramsbotham, Granville, Ashwell, Lever, Locock, Waller, Murphy, Tyler Smith, Oldham.

These men all lived so near our own times (at least those of us who, like myself, have reached the grand climacteric), that the bare mention of their names at once recalls the titles and the nature of their respective contributions to the funded capital of our professional knowledge.

Of the living obstetric celebrities, who make this city the scene of their work and their influence, I purposely refrain from speaking: —

"My thoughts are with the dead; with them
I live in long past years,
Their virtues love, their faults condemn,
Partake their hopes and fears;
And from their lessons seek and find
Instruction with an humble mind."

(SOUTH.)

But, to a more worthy occupant of this chair at some future meeting of the Congress, after we have played our little parts in life's drama, I bequeath the grateful, pleasing task of supplementing the above list with the names of those eminent London obstetricians and gynaecologists, whom to meet and to know is assuredly the most gratifying of the many privileges connected with this great international gathering.

"THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

INAUGURAL ADDRESS IN THE SECTION OF ANATOMY.

BY PROF. W. H. FOWLER, LL. D., F. R. S., F. R. C. S., ETC.,
President of the Section.

While thinking over various subjects for an address with which to open the business of the section over which I have the honor to preside, it has occurred to me that the time which has been allotted by the arrangements of the Congress for the purpose, may be made most useful to my hearers, if, instead of entering upon a discussion of any abstract question, I were to ask your attention to a subject upon which I may possibly be able to give a little information of practical use to members of the Congress during their visit to this city.

No class of persons can appreciate so fully the importance and value of museums as those whose occupation it is to study the form and relations of the various parts of the body, whether of plants, animals, or man.

Our science would make little progress if the objects of our inquiries, once used for examination or description, were then thrown aside, and those coming after were denied the opportunity of which we have availed ourselves. A museum is a register, in a permanent form, of facts, suitable for examination, verification, and comparison one with another.

Hence, ever since serious attention has been awakened to the interest of anatomical studies, museums have always been important adjuncts to their successful prosecution, and the preservation of the various structures of the body has occupied the attention of very many anatomists, since the time of the great Italian teachers of the early part of the seventeenth century, with whom, apparently, the art commenced.

We have in London, as you are all aware, a museum which stands, in some respects, in a peculiar position, differing perhaps from any in the world in its origin, its scope, its method of maintenance, and its relation to the profession and to the state, in which, for very nearly twenty years, it has been my privilege to pass my days. It has occurred to me that a few words in explanation of the history, arrangement, and contents of that museum might add to the interest and profit of those visits which I trust every one here will find time to pay to it during the meeting of the Congress.

The great mind of John Hunter, far in advance of his age, — and, it may be, even of ours, — saw at one glance the vast importance of biological science, and the best means to further its pursuit. To this end he founded his museum, and directed by his will that it should always be maintained in its integrity. Wherever civilized men are gathered together there are now minds who feel what Hunter felt. The necessities of such minds have created in every country in Europe, and the enlightened parts of the New World, museums designed to serve in their different degrees the same functions as our Hunterian collection. Such museums are evidently national needs; they have already come, though not by any means to the extent they will in future come, to be looked upon as an essential portion of the educational machinery of the state. Such museums are, in almost every capital of Europe, supported directly at the expense of the state, or are connected with some great educational institution dependent upon Government for aid. In England alone the need has

¹ Slightly condensed from the advance sheets.

been supplied, first, by a private individual, and secondly by a private, or semi-private institution, composed of members of a single profession, with only occasional assistance from the state. In this country the state (and therefore every individual composing it) is indebted to John Hunter and the Royal College of Surgeons for relieving it of the burden, which must otherwise have fallen upon it, of providing that portion of the national education afforded by a biological museum.

The period occupied by John Hunter in the formation of his collection was all comprised between thirty years — 1763, the date of his return from service with the army in Portugal, and 1793, that of his death. The labor which he accomplished during this time was something prodigious, as has often been recounted in various biographies and Hunterian "orations." Notwithstanding all that has been written and said, it is impossible to do justice to his wonderful activity and industry. In nothing, however, were these qualities so conspicuous as in the formation of his museum.

Public museums at that time scarcely existed. The British Museum was little more than a library and gallery of art: the small cabinet of natural history, reinforced by the old collection of the Royal Society, scarcely made any show. Anatomical specimens, even bones and teeth, were looked upon with disfavor. Some that had accidentally found their way into the collection were, even within the present century, treated as intruders, and turned out without much ceremony.

Teachers of anatomy were forming their own private collections, but these were all eclipsed by those of the two Hunters, William and John. That of the latter, especially, grew to such an extent as to become in some sort a national and public institution. He built a large room to contain it in Castle Street, at the back of his house in Leicester Square, and when finally arranged there, so much interest was taken in it that he found it necessary to open it to public inspection at certain stated times. Still it was maintained entirely at his own cost, and it is stated that by the time of his death he had spent upwards of £70,000 upon it. Whether this estimate be correct or not, his expenditure on it must have been very great, as, though he had for many years made one of the largest professional incomes in London, his museum was the sole property he left behind.

John Hunter was a very miscellaneous collector — minerals, coins, pictures, ancient coats of mail, weapons of various dates and nations, and other so-called "articles of *virtu*" engaged his attention. These, however, and his furniture and books, had to be sold to meet the most pressing needs of the family. What would be now called the "biological" part of his collection was kept intact, during the six years which elapsed between his death and its purchase by the English Government in 1799. The preservation of the collection during this period is mainly due to the devotion of William Clift, Hunter's last assistant, whose services were retained for this purpose at a very small salary by the executors, Sir Everard Home and Dr. Matthew Baillie, and whose fidelity was rewarded by his being appointed the first "Conservator" of the collection after it came into the possession of the College of Surgeons.

The story of the negotiations with a government whose interests and energies were then concentrated

upon the great Continental war, and the answer of the Prime Minister Pitt, when applied to on the subject, "What! buy preparations! Why, I have not money enough for gunpowder," are well known. These difficulties were, however, overcome, and on the recommendation of a committee of the House of Commons appointed to inquire into the subject, the sum agreed to by the executors, namely, £15,000, was voted for its purchase on the 13th of June, 1799. Then came the question what was to be done with it. There was at that time no department of government under the care of which such a collection could be placed. The condition of the British Museum has been already alluded to. The now flourishing and all-absorbing "department of science and art" had not been invented. There was one body in London which might be supposed to have some special interest in the maintenance of such a collection, — the venerable and dignified College of Physicians, — but that body, it is commonly reported, demurred to accept it on the ground of want of funds to meet the annual expense of its maintenance. With reference to this report Dr. Pitman has been kind enough, in response to my inquiries, to examine the archives of the College, and finds that there is no record of any such offer having been made or refused. If any negotiations were entered into they must, therefore, have been of a purely informal nature.

There was still another corporate body, — a comparatively obscure one at that time, — the Corporation of Surgeons, which had only separated itself some fifty-four years before from the old City Company of Barbers and Surgeons,¹ and although it had thrown off the connection which restrained its members from assuming the position of cultivators of a liberal profession, it had as yet done little to raise itself in public estimation, and had few resources from which to provide for the expenses of such a collection. Nevertheless, the Court of the Corporation determined by a unanimous vote on December 23, 1799, to accept the Museum on the terms proposed by the government, and almost simultaneously obtained a new charter, under which they became The Royal College of Surgeons, a body accredited by government to examine all persons wishing to practice surgery in the kingdom, and migrated from their old quarters in the city to the house in Lincoln's Inn Fields, round which the present establishment has grown up.

Thus John Hunter's Museum and the College of Surgeons of England, though of entirely independent origin, have had their fortunes inextricably intermixed, since the former became national property, and the latter took the title and position it now holds.

The College is still the principal examining body for those who practice surgery throughout the kingdom. It takes no part directly in professional education, though it exercises a considerable indirect influence by the manner of conducting its examinations, and by the

¹ By an act of Parliament, passed in the eighteenth year of the reign of George II., entitled "An Act for making the Surgeons of London and the Barbers of London two separate and distinct Corporations," it was enacted that the union and incorporation of the Barbers and Surgeons of London, made by the Act of the thirty-second year of King Henry VIII., should from and after the 24th day of June, 1745, be dissolved, and that such of the members of the said united Company who were Freemen of the said Company, and admitted and approved Surgeons, within the Rules of the said Company, and their successors, should from thenceforth be made a separate and distinct Body Corporate and Commonalty Perpetual, which at all times thereafter were to be called by the name of "The Master, Governors, and Commonalty of the Art and Science of Surgeons of London." The first Charter of the Company dates from the first year of the reign of King Edward IV. (A. D. 1461).

curriculum it requires from candidates. Its revenues are mainly derived from the fees paid for the diplomas which it grants, which, for the last ten years, have averaged three hundred and eighty-three a year. In former times these fees considerably exceeded the expenses of the comparatively slight examination required from candidates, and the surplus, besides defraying the current expenses of the Museum and Library, was devoted to the erection of the present buildings, and the acquisition of the freehold property and invested capital of the College. It says much for the personal disinterestedness of the eminent members of the surgical profession who have constituted the Court of Examiners, and who until very lately were practically the ruling body of the College, that they fixed their own remuneration at so low a rate as to permit an expenditure during the present century upon the purposes just indicated of a sum which cannot be estimated at less than £100,000. Now, owing to the more searching and practical character of the examinations, the expenses of conducting them have augmented to such an extent as to be scarcely more than covered by the payments of the candidates; and but for the proceeds of the investments made under different circumstances, the College would not have the means of carrying on the scientific work it has undertaken.

The various professorships and lectureships that are attached to the College have grown up chiefly in consequence of one of the conditions under which the Hunterian Collection was entrusted to it by government, — that a course of no less than twenty-four lectures shall be delivered annually by some member of the College upon comparative anatomy and other subjects, illustrated by the preparations. Other lectureships have been founded by private benefactions, but these are of limited number, or on special subjects, and are intended, not so much for the education of students, but rather as the means of introducing new discoveries or ideas to members of the profession and others interested in scientific pursuits, to all of whom they are freely open without payment.

Besides the Museum, the College has added to its means of benefiting its own members and the profession generally, a library containing every important work and periodical upon surgery, medicine, anatomy, and the collateral sciences.

During the first six years after the collection came into the possession of the College it remained in the gallery in Castle Street, which had been built by Hunter for its reception; but in 1806, the lease of the premises having expired, it was removed temporarily to a house in Lincoln's Inn Fields, adjoining the College of Surgeons, while the building in which it was destined to be lodged was preparing for its reception. This building, towards the erection of which Parliament contributed the sum of £27,500, was completed and first opened to visitors in 1813.

The Museum was greatly enlarged, entirely at the expense of the College, in 1835, and a still more important addition, that of the great eastern hall, was completed in 1855. Towards the expense of this Parliament contributed a further grant of £15,000, the whole of the rest of the expenses of the purchase of the site, the building, and the annual maintenance of the Museum having been borne by the College.

In keeping the Hunterian Collection, the College of Surgeons undertook a heavy responsibility, weight-

ier perhaps than was contemplated at the time. Although not required by the letter of the contract to do more than preserve Hunter's specimens, the College undertook the charge in the spirit of the founder, and thus made itself responsible for maintaining such a collection as should meet the requirements of the ever-expanding and vigorous young science to which it ministers. Hunter's collection was held to be the nucleus of a national biological museum, and its preservation and augmentation by the College has certainly prevented the formation of such a collection by the state.

Hunter was no specialist, and even after eliminating the non-biological subjects before alluded to, a very miscellaneous collection remained: illustrations of life in all its aspects, in health and in disease; specimens of botany, zoölogy, paleontology, anatomy, physiology, and every branch of pathology; preparations made according to all the methods then known; stuffed birds, mammals, and reptiles, fossils, dried shells, corals, insects, and plants; bones and articulated skeletons; injected, dried, and varnished vascular preparations; dried preparations of hollow viscera; mercurial injections, dried and in spirit; vermilion injections; dissected preparations in spirit of both vegetable and animal structures, natural and morbid; undissected animals in spirit, showing external form, or awaiting leisure for examination; calculi and various animal concretions; even a collection of microscopic objects, prepared by one of the earliest English histologists, W. Hewson.

It is very difficult to compare the present Hunterian Museum, as it is still often called, although officially only recognized as the Museum of the Royal College of Surgeons of England, with any other existing collection, as its nature and the character of its contents have been determined by several accidental circumstances rather than by any very settled purpose. Originally a private collection, embracing a large variety of objects, it has been carried on and increased upon much the same plan as that designed by the founder, with modifications only to suit some of the requirements of advancing knowledge. The only portions of Hunter's biological collection which have been actually parted with are the stuffed birds and beasts, which were transferred to the British Museum, and a considerable number of dried vascular preparations, which, having deteriorated from age and decay, have been replaced by others preserved by better methods. Of the various departments of which the Museum now consists, very few, in fact only the collection of illustrations of skin diseases, and the collection of surgical instruments, are not the direct continuation of series founded by John Hunter.

To find an analogous institution to the Museum of the College of Surgeons, in Paris, for instance, we should have to combine the collections of comparative anatomy and anthropology at the Jardin des Plantes, and even a portion of the separate paleontological collection at that establishment, the collection of human anatomy of the Musée Orfila, and that of pathological anatomy of the Musée Dupuytren. If these were all brought together under one roof, and somewhat compressed and rearranged, we should have something in its nature resembling the Museum of which I am now speaking.

In this combination on one spot, and under one management, of so many diverse collections, we have

a survival of a condition of scientific knowledge more characteristic certainly of the last century than of the one in which we live; but in this age of specialities it is well perhaps to be reminded by such an institution of the essential unity of biological knowledge, and of the important illustrations which one branch of it may afford to another, especially when the detailed facts are to be combined for the purpose of philosophical generalization.

In visiting the Museum, and in the comparison which may be instituted between it and others of its kind, it is important to recollect this origin and history, as they will account for many shortcomings. It must not be forgotten that to its comparative antiquity (for it is certainly the predecessor and prototype of all the anatomical museums of this country and of America, and to most of those on the Continent) is due many faults of construction and arrangement which should not be found in a building designed with the knowledge and experience of recent years. I have elsewhere pointed out what I consider the chief of these.¹

Though the large size of the principal rooms allows of a fine *coup d'œil*, such a construction does not permit of that separation and distribution of the different series which is desirable for the purposes of study. Human anatomy, invertebrate zoölogy, and pathology, for instance, come into such near juxtaposition as to produce some confusion in the minds of strangers, though familiarity with the arrangement soon disperses the difficulties at first met with in finding the situation and limits of the particular department required. The narrowness and unprotected condition of the shelves in the galleries is also a radical defect now, unfortunately, irremediable. Furthermore, the indulgence of those who have the happiness to live elsewhere than in the absolute centre of a population of four millions of coal-burning people must be asked for certain dusky results of such a situation, which no amount of care and expense can obviate.

I must now ask leave to be your guide to some of the contents of the Museum, as it is at present arranged, and will take the different branches of biology which are illustrated in it in some kind of order, beginning with the part which relates to life in a normal condition. Hunter's collection and observations were not limited to the animal kingdom. Wherever any physiological process could be illustrated by vegetable life, vegetables were pressed into the service, as may be seen in the physiological gallery, and by the Memoranda on Vegetation left by him in MS., and printed by the College in 1860. In his collection were many portions of various recent plants, and a series amounting to 184 in number of fossil woods, fruits, and impressions of stems and leaves. These specimens, with some additions made in former years (for since the great development of the parts of the Museum more essential to the general purposes of the institution, it has been necessary to restrict the growth of such branches as are more fully and advantageously illustrated elsewhere) are arranged in the large wall-case on the right hand side (on going in) of the entrance door of the first or western hall.

The zoölogy of invertebrate animals largely attracted Hunter's attention. Many of the treasures collected in the famous voyages of Captain Cook came into his possession through his friend, Sir Joseph Banks. He purchased, whenever opportunity offered, as at the

sale of Mr. Ellis's famous collection of corals and zoophytes. In 1786, at the sale of the Duchess of Portland's museum, he bought, for fifteen guineas, the fine *Pentacrinus* now in the Museum, of which very few examples had then been found. Of insects, especially *Lepidoptera*, he had a large series. Of fossil invertebrates, as many as 2092 specimens are now recorded in the catalogue as Hunterian. The series of fossil cephalopods is remarkably rich.

Such invertebrate animals as are dissected or illustrate any special anatomical fact, are arranged in the so-called physiological series in the gallery, to be described presently, but beyond these there remained a vast number of specimens only showing external form, which by selection and arrangement have been lately formed into a special zoölogical collection, intended to introduce the student to a general knowledge of the principal forms of animal life, and to the mode in which they are grouped.

Although locally far removed, occupying one portion of the upper gallery of the middle Museum, a small but interesting special collection, illustrating the subject of helminthology, may be mentioned here. It was thought that the importance in a medical and social point of view of those animals which infest the interior of man and the principal domestic and other animals, justified a more extended exhibition of their modifications than could be assigned to any other group of animals of such inferior organization, and by the aid of the well-known helminthologist, Dr. Spencer Cobbold, the present collection was arranged and catalogued in 1866, the materials being mostly already in the collection, though scattered in other series or hidden in the storerooms. The collection contains upwards of two hundred specimens, and may still be somewhat extended. The intention is to show every parasitic animal which, under any circumstances, can affect the human body, and a selection of the principal types of those that inhabit the lower animals, especially such species as are associated with man. If increased beyond these limits, the collection would become interesting only to the student of detailed systematic zoölogy, and therefore not a legitimate object for our Museum.

I will pass next to the section of the Museum which is, perhaps, altogether the most characteristic, and is certainly the most eminently Hunterian. It was specially the creation of his mind, is still arranged almost exactly as he left it, and, notwithstanding the very numerous additions, still contains a larger proportion of Hunterian specimens than any other department. This is the collection which is called *Physiological*, because the specimens in it are classified mainly according to their supposed function. Physiology, as we know it now, is scarcely a subject which can be illustrated in a museum. The processes and actions which take place in the living body are not to be shown in bottles, but the organs, through the medium of which physiological processes are performed, can be, and it is these which are illustrated in this collection. It is more truly a collection of comparative anatomy, or morphology as we should now call it. It shows the variations in form which the different organs undergo either in different species, or in the same species under different conditions, as age and sex or season. Many of these modifications clearly have relation to function, as we see in the difference of form and relative size of the compartments of the stomach of the young rumi-

¹ Journal of Anatomy and Physiology, vol. ix., May, 1875.

nant, which is nourished by milk, and the adult, which feeds on grass, the periodic variations in the size of the testis in birds, etc. But in a vast number more we can see no special adaptation to purpose, but merely variation, apparently for variety's sake. Look, for instance, at all the differences of the form of the liver throughout the mammalian series, which, as far as we know, have no relation to its action as a secreting gland. Though of little interest to the physiologist, modifications of this kind are of the highest importance to the morphologist. They throw light upon one of the great biological problems, classification, which, when rightly interpreted, means nothing more or less than a statement of the order in which living beings have been evolved one from another. From such variations of form most precious indications of the relationship of one animal to another can be obtained, and the less these variations are related to adaptation to some particular function, the better they can be relied on for this purpose. But Hunter's ideas were far different. He tried to bring together analogous parts according to their uses. — organs of progressive motion adapted for flying, eyes modified for seeing in water, eyes modified for seeing in air, etc. Practically, such a system could not be logically carried out. Too many modifications of form were found to occur, to which no special modification of function could be assigned, a compromise had to be made, and in the large number of cases the organs had to be arranged according to the affinities of the animals to which they belonged — brains of fishes, brains of birds, brains of mammals, etc. As the collection continues to advance, the classification according to homology is gradually superseding that according to analogy, with which it began.

This collection at present contains 6982 specimens mounted in bottles, of which 3745, or more than one half, are Hunterian. It may be convenient to know that these are distinguished by the figures upon them which refer to the catalogue, being painted in black. The specimens added since Hunter's time are lettered in red. The greater number of the former must be fully a century old, and being still in as perfect preservation as when first put up afford a fair guarantee of the absolute permanence, with proper care, of specimens preserved in alcohol. The skill displayed in dissecting, injecting, and mounting the majority of these preparations has scarcely ever been surpassed in modern times, and this collection alone, if it were all that Hunter had left, would be a grand monument to his industry and zeal for anatomical knowledge; as is its valuable and instructive descriptive catalogue, published in five volumes, and completed in the year 1810, a lasting evidence of the same qualities on the part of Mr. Cline's eminent successor in the conservatorship of the museum, Professor Owen.

Many points in comparative anatomy can be illustrated quite as efficiently, and more economically, by dried preparations, which require neither spirit nor bottles to preserve them in. Though we have not attained in this country the art of making such preparations in the elegant and instructive manner pursued in several of the museums in Italy, notably Pisa, and though nearly all the original Hunterian dried preparations have perished long ago, or become partially useless, there will still be found some worthy of attention in the rail cases round the galleries which contain the dried preparation. While speaking of the contents of these cases I would specially call attention to the series

showing the modifications of the small bones of the ear, throughout the mammalian class, arranged a few years ago by Mr. Alban Doran, one of the assistants in the museum, which is, probably, not surpassed in extent or variety and method of arrangement anywhere else.

The Histological Collection consists of upwards of 12,000 specimens, mostly prepared under the direction of Professor Quekett, who devoted the greater part of his life to this work. Since his death, in 1861, the additions have not been numerous, chiefly in consequence of the difficulties in exhibiting such a collection.

Although the anatomy of man naturally takes its place among that of other species in the physiological series, the preparations illustrating it are chiefly confined to viscera — the details of regional anatomy, and of the arrangement and distribution of muscles, vessels, and nerves, not finding a natural place in the scheme upon which that department of the Museum was organized. It was, however, a few years ago, thought desirable that human anatomy, in consideration of its great importance to our profession, should be exhibited on a much more extended scale than it had been hitherto, and that a ready demonstration should be afforded by means of permanent preparations of the structure of all parts of the human frame. To those who have already learnt their anatomy, and who wish to refresh their memory, or verify a fact about which some passing doubt may be felt, or those who are precluded by circumstances from visiting the dissecting-room, the preparations of this series must prove of great value. The series of dissections already made with this end, commenced by a former able assistant in the museum, Dr. J. Bell Pettigraw, and carried on to their present perfection by Mr. W. Pearson, are arranged on shelves over the floor cases on the western side of the Western Museum contiguous to the series of human osteology, to which they form the natural sequel.

No portions of the structure of vertebrate animals can be preserved with greater facility than the bones and teeth. Moreover, the skeleton being the framework around which the rest of the body is built up, gives, more than any other system, an outline of the general organization of the whole animal, and it has this special importance, that a large number of species — all those in fact which are not at present existing upon the earth — can be known to us by little beyond the form of the bones. Osteology has, therefore, always had many votaries, as a special branch of study, and it is one which finds much favor in the eyes of curators of museums, from the satisfactory manner in which it can be illustrated by specimens. Hunter's osteological collection was considerable, quite in advance of any other in this country. The two small whales (*Balenoptera rostrata* and *Hyperoodon rostratus*) which formed part of it, were almost the only skeletons of animals of their order which existed in any museum at the time of his death. This fact alone shows the marvelous change that has taken place within less than a century in the facilities for the study of comparative anatomy. How great the contrast to what may now be seen here in the College of Surgeons, in the British Museum, in Oxford, Cambridge, Edinburgh, Dublin, in a score or more of museums on the European continent, in America, even in Australia and New Zealand! Richly supplied osteological collections have sprung up in every considerable centre of scientific culture over the world; but as ours was one of the first in point of time, we may also claim for it a high position in point

of completeness. Others, such as that at the British Museum, the Jardin des Plantes at Paris, and the famous Leyden collection, may be larger, but this is because the College Museum has been designedly limited rather to selected illustrations of all the most important modifications of structure, than to numerous examples of closely allied species, which may be perfectly necessary in a purely zoological museum. When important forms have become extinct, their characters are shown by their fossilized remains, which, though at present most illogically arranged in a distinct room apart from their existing allies, will soon be incorporated in the general osteological series, where alone they can find a reasonable position in an anatomical museum.

The value of a collection is not to be estimated only by the number of specimens it contains, nor by even their rarity or judicious selection, but also by the condition of the specimens, and the facility by which they may be made available for study and reference. On this head we claim to be somewhat in advance of other museums, on account of the improvements which have been made in late years in preparing and articulating entire skeletons, and displaying portions of the bony framework in an instructive manner. Formerly all the bones were rigidly fixed together, so that their articular surfaces, if not actually destroyed, were completely concealed; and no bone could possibly be removed and separately examined. The aim of a series of changes in the method of mounting skeletons introduced here, and now adopted more or less completely in many other museums (the details of which were carried out with great skill by our late able articulator, Mr. James Flower), has been to obviate all these difficulties, and to make each bone, as far as possible, independent of all the rest, while preserving the general aspect and form of the entire skeleton.

Another improvement in the osteological series, introduced within the last twenty years, has been the formation of a special collection designed to show the principal modifications of each individual element of the skeleton throughout the vertebrate classes, by placing the homologous bones of a number of different animals in juxtaposition. For convenience of comparison, the specimens of this series are all placed in corresponding positions, mounted on separate stands, and to each is attached a label bearing the name of the bone, and the animal to which it belongs. This series is especially instructive to the students of elementary osteology, and forms an introduction to the general series.

As in other departments of the Museum, the more nearly man is approached in structure, the more complete do the illustrations of anatomical modification become, and, as might be expected, the osteology of man is far more thoroughly shown than that of any other species. The specimens of human osteology (of which a revised catalogue, enumerating 1306 specimens, was published two years ago) begin by illustrations of the development of the bones; these are followed by the normal skeleton, exhibited under various aspects, then by individual variations, among which may be mentioned one of the most remarkable objects in the museum, the skeleton of the celebrated Irish giant, O'Brian, who died in London in 1783, and about the preservation of whose remains so many legends are told in the biographies of John Hunter. Finally, the special osteology of man or illustrations of the osteo-

logical characters of the various races of mankind. In this important subject Hunter was a long way in advance of most of his contemporaries, as the origin of his collection dates almost, if not quite, as far back as that of the founder of physical anthropology, the celebrated Blumenbach. The series has been greatly augmented of late years, and completely rearranged, and the splendid addition made to it last year, by the purchase of the great private collection of the late Dr. Barnard Davis, has brought it up in point of completeness to truly national importance.

As forming a transition from the department of normal anatomy and physiology to that of pathology, may next be mentioned the teratological series, or collection of congenital malformations of man and the lower animals, which necessarily forms a part of every general biological museum. This difficult, mysterious, — and as far as the light it throws upon the workings of the laws of nature, — still unsatisfactory subject, had considerable attraction for Hunter, and many of the specimens in the series formed part of his museum. It has been steadily, though not very rapidly, increasing ever since, and had the advantage a few years ago of being thoroughly revised, rearranged, and catalogued by Mr. B. T. Lowne. It is arranged in the upper gallery of the Middle Museum.

The pathological series is the section of the Museum, to the study of which in the eyes of Hunter and his successors all the others form an introduction. It occupies the whole of the two galleries and part of the ground floor of the western hall. As the Museum of the College differs from those attached to the various medical schools, in having no hospital or *post-mortem* room in connection with it, from which to draw the supplies for completing this collection, it has been increased by the acquisition from time to time, when opportunity afforded, of various private collections, as those of Mr. Heavyside in 1829, Mr. Langstaff in 1835, Mr. Howship and Mr. Taunton in 1841, Mr. Liston in 1842, and Sir Astley Cooper in 1843, obtained by purchase; and the collections of Sir William Blizard in 1811, Sir Stephen Love Hamminck in 1851, and Dr. Peacock in 1876, presented to the College. Contributions of recent specimens are also constantly received from numerous individual donors, the acquisitions from this source having greatly increased of late years. The total number of specimens now in the catalogue amounts to 5148, of which 1672 are Hunterian. As in the physiological galleries, the latter are distinguished by their numbers being painted in black. The descriptive catalogue of this series, written by Sir James Paget, and published in five quarto volumes between the years 1846 and 1849, is one of the best known and most valuable of all the publications of the College, and has always been looked upon as a model upon which other pathological catalogues should be formed. The additions made to the collection since that time have been so numerous that the necessity of a new catalogue has long been felt. Under these circumstances, it is a matter of great congratulation to all who are interested in the welfare of this valuable collection, that the author of the original catalogue has undertaken, with the coöperation of Dr. Goodhart and Mr. Doran, to make a new one, in which the old descriptions will be revised, the new specimens incorporated in their appropriate places, and such changes introduced into the general arrangement as the advance of pathological knowledge and greater experience of

the requirements of the Museum appear to necessitate. This great work, especially arduous for one so much engaged in professional avocations as Sir James Paget, is now far advanced. The prospect of its early completion will doubtless compensate the members of the Congress who will make an inspection of this part of the collection, for the transitional and somewhat disarranged condition in which they will find it on their present visit.

As adjuncts to the general pathological series are certain special collections, which have separate catalogues devoted to them. One, which will be examined with interest by those devoting themselves to aural pathology, is the series of preparations illustrative of diseases of the ear, formed by the late Mr. Joseph Toynbee; which came into possession of the College at his death in 1866. It is a large and probably unique collection of 824 specimens, illustrating all the known morbid conditions of the organ of hearing, such as could only have been brought together by one specially engaged for a considerable number of years in investigating this branch of surgery, and the value of which is greatly enhanced by a complete descriptive catalogue, published during Mr. Toynbee's life-time.

Lastly, must be mentioned a collection—for the reception of which a separate room, approached from the end of the Eastern Museum, was devoted in 1870—of surgical instruments and appliances, which, though small at present, contains many instruments curious for their antiquity, or interesting for their associations, and, doubtless, now that a convenient and appropriate locality has been established for their reception and preservation, will be gradually augmented by additions of a similar nature. It is mainly to the interest taken in the subject which it illustrates by the late Sir William Fergusson that the establishment of this collection is due.

Such is a general outline of the history and contents of the Museum which, for eighty years, the College of Surgeons has maintained for the benefit not only of its own members, but for that of the profession at large, and, indeed, of all who take any interest in biological science, whether the young student preparing for his examination, or the advanced worker who has here found materials for many an important contribution by which the boundaries of knowledge have been materially enlarged. To all such it is freely open without any fee or charge. Even the written or personal introduction of members, still nominally required, is never asked for on the four open days from any intelligent or interested visitor; and on the one day of the week in which it is closed for cleaning, facilities are always given to those who are desirous of making special studies, and to the increasing number of lady students, whether artistic, scholastic, or medical. Artists continually resort to the museum, to find opportunities of studying the anatomy of man and animals, which no other place in London affords; and of late years it has been the means of a still wider diffusion of knowledge, by the visits which have been organized on summer Saturday afternoons by various associations of artisans, to whom a popular demonstration of some part of its contents is usually given on each occasion by the conservator.

If the knowledge of organic nature is of any value to man, and this is a proposition which I am sure all who attend this Congress will admit, as on such knowledge the whole superstructure of their profession is

built, there can be no question but that such an institution as I have here sketched out, must be one of pure and simple benefit. Its maintenance has been a worthy object, upon which the College has spent its care and its money, and whatever may be the changes which impending legislation may effect in the organization of the profession, we may all hope that the great work begun by John Hunter, and carried on by those who, under the guidance and support of the council of the College, have followed him in the care of the collection, may not be impaired or destroyed. Whether the whole of the charges of maintaining such a museum in all its parts on a continually extending scale should be the duty of one institution, like the College of Surgeons, or even of one profession, may be a question for future consideration; but, in the mean time, how easily could its preservation and future extension be rendered entirely independent of all the chances and changes of medical education and legislation, or even of Government assistance and interference! When we see the immense sums voluntarily provided every year in this country by donation and bequest; when we see, and see with pleasure and gratitude, through the length and breadth of the land, cathedrals, churches, chapels, colleges, schools, hospitals, and asylums founded, endowed, enlarged, and restored, may we not hope that an old and tried institution like ours will not be so entirely neglected as it has hitherto been by members of our profession in search of some means for the disposal of any surplus wealth they may possess. Few objects can be so surely productive of good, so little liable to abuse at any future time, as the preservation, augmentation, and maintenance of a museum in which the facts of the beautiful and wonderful world around us are displayed for the instruction of mankind.

Recent Literature.

American Nervousness, its Causes and Consequences. A Supplement to Nervous Exhaustion (Neurasthenia). By GEORGE M. BEARD, A. M., M. D. New York: G. P. Putnam's Sons. 1881. Pp. xxii., 352.

Dr. Beard omitted the chapter on *Ætiology* from his book on *Neurasthenia*, and this volume is intended to supply that omission, but it does much more. A general review of "nervousness," its nature, the signs of its presence, its causes and effects, are given, among the latter being probably included the chapter on the longevity of brain workers, and the relation of age to work.

In a general way the book is interesting reading,—the author expresses his views with the enthusiasm of conviction, and so arouses interest,—it is broken up into short sections, the language for the most part is simple, and it is not difficult to understand the author's meaning. He has brought together a large number of facts and statements, many of which deserve attention, and the more thought there is given to many of the propositions advanced the more important they will appear.

Several times the author makes complaint that previous writings of his have not received the acceptance they deserved as scientific facts. There are probably two reasons for this, which will equally interfere with the acceptance of his views as expressed in the present work. Many of the statements made are such as not

to be susceptible of universally convincing proof. They are simply the views of a specialist who has seen one side of the problem of social life and health much more clearly than any other side thereof, and who states his impressions accordingly. It is not strange that other observers, working under different conditions, having different phases of health or disease brought to their notice, should differ with him; that they should consider a neurologist too prejudiced to judge accurately as to the increase and prevalence of nervousness. Where only impressions and opinions are stated it would require time before others should be able to see the same facts in the same light, and so be able to give assent to the views expressed.

The second hindrance to a speedy acceptance of the views advanced is the absence of scientific data in the book. Opinions are given, statements are made as to facts coming within the author's observation, but not so as to bring conviction of their accuracy to one who has not observed the same facts, or who may interpret these facts differently. Even where it were possible to establish the truth of his propositions — in regard to the longevity of brain workers — the author has not given the data upon which he bases his statements; the list of names, with the ages of the persons whose lives he has studied with reference to this theory should have been given, in order to convince the skeptical and to establish his theory.

In the preface he "epitomizes the philosophy of the work." Nervousness is strictly deficiency or lack of nerve force. This condition has developed mainly with the nineteenth century. Nervousness is to be distinguished from simple excess of emotion and from organic disease. The chief and primary cause of this increase of nervousness is *modern civilization*; among the secondary and tertiary causes are climate, institutions, personal habits, etc. These secondary and tertiary causes cannot alone induce nervousness. The signs of American nervousness are considered at length, among which are many apparently trivial signs, or signs to which not everybody would ascribe importance, as early and rapid decay of teeth, premature baldness, sensitiveness to cold and heat, increase of certain diseases, as diabetes and certain forms of Bright's disease, unprecedented beauty of American women, frequency of trance and muscle-reading, American oratory, humor, speech, and language. There is much that is interesting in the chapter where these signs are considered, much that is true and deserving of consideration.

The longevity of brain workers and the relation of age to work is a subject to which Dr. Beard has previously given considerable attention; his conclusions, drawn from studying the lives of very many eminent men, are decidedly in favor of the tendency of brain work to promote long life. The average longevity of all classes he places at a little over fifty-one years. One hundred of the greatest men of the world lived on an average seventy-five years; one hundred and fifty precocious great men lived 66.5 years; five hundred great men lived 64.2 years; clergymen live six-four years; farmers sixty-four; lawyers fifty-eight; physicians fifty-seven years. The greatest amount of original work he finds is done between the ages of thirty and fifty years, most of it before the forty-fifth year.

The book closes with a chapter on the physical future of Americans, in which a very comforting view is taken of our future prospects. "Applying the omnistic phi-

losophy (by omnistic the author means to include both optimism and pessimism, the word is not a misprint for optimistic) to our subject, we find that the American people are not coming to complete and immediate overthrow; the forces that renovate and save are mightier far than the forces that enervate and destroy. Although mental friction is the most fruitful source of all causes of nervousness, yet the intellectual activity in the serene realms is an antidote and a modifier of nervousness and other diseases."

The next paragraph to the above reads almost as if optimistic was meant instead of "omnistic." "It is not a dream to predict that, under the inspiration of the scientific sense, the last and best expression of the evolution of mind, there shall be developed on this continent a higher order of humanity from which shall be developed what the world, thus far, has never seen, a limited number of philosophers who, in all the eternal problems, shall think for themselves, as though the gods were blind, and they were alone upon their footstool."

This will serve as a single example of some passages in which the author's enthusiasm seems to run away with his common English sense, and he degenerates into spread-eagle style of writing. S. G. W.

A Medical Formulary based on the United States and British Pharmacopœias, together with numerous French, German, and Unofficial Preparations. By LAWRENCE JOHNSON, A. M., M. D. New York: William Wood & Co. 1881. Pp. 402. 8vo.

The design of this work, according to its author, is to present in a manner convenient for ready reference the drugs and preparations in common use, together with formulæ illustrating the manner in which they are combined by good practitioners of the present day. This is fairly accomplished by aid of its very full index.

Although it contains much valuable information for the discerning physician which is not to be found in the United States or National Dispensatories, yet like all formularies it is open to the objection of offering encouragement to the all too common routine practice of copying certain favorite recipes for the treatment of certain diseases without the making of the proper allowances for the ever-varying aspect of the individual cases. Moreover, this particular work mingles indiscriminately recipes made up in the like terms for weight and measure of the troy and avoirdupois weights and the wine and imperial pint measure. This is very liable to cause mistakes to be made by those using the book, as recipes written in the terms of the British Pharmacopœia are likely to be dispensed as if written in the same terms of the United States Pharmacopœia. This in very many cases can be avoided only by the knowledge of an expert in the names of hospitals and physicians that the separate recipes are of British and not of American origin, for there is nothing else to distinguish them. B. F. D.

Landmarks, Medical and Surgical. By LUTHER HOLDEN, assisted by JAMES SHUTER. Third Edition. Philadelphia: Presley Blakiston. 1881.

The paper and printing of this edition are very handsome. The text differs but slightly from that of the second. The merits of this book are too well known for it to require further comment. T. D.

Medical and Surgical Journal.

THURSDAY, AUGUST 18, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE OPENING ADDRESSES AT THE INTERNATIONAL MEDICAL CONGRESS.

HAVING received advanced sheets of the addresses delivered by the president of the Congress and by the presidents of some of the Sections on the first day of the meeting of the International Medical Congress at London, the JOURNAL is enabled to offer its readers the perusal of these at an earlier date than they could otherwise see them, especially as with this end in view the day of publication of the present number has been advanced.

We feel that the character of some of these addresses will reconcile our readers to the postponement of the original articles to which the first part of the JOURNAL is usually devoted. That of the president, Sir James Paget, is a really noble production, in every way worthy of the occasion and of its author's reputation. It is broad, liberal, and elevating, and at the same time perfectly simple and concise. The addresses at the opening of the Sections are not all of equal merit or equal importance: if we ventured to single out any to which to call special attention it would be that of Dr. Samuel Wilks to the Section on Pathology, and of Mr. Erichsen to the Section on Surgery.

The meeting which has just taken place in London is, if the Medical Congress at Philadelphia during our Centennial celebration be excepted, the seventh consecutive International Medical Congress which has been held.

The idea originated at the annual meeting of the French Medical Congress at Bordeaux, in 1865. In 1867 the first Congress was held at Paris during the Exhibition. The second Congress was held at Florence in 1869, the third at Vienna in 1873, during the Exhibition there; the fourth at Brussels, in 1875; the fifth at Geneva, in 1877; and the sixth at Amsterdam, in 1879. Since 1873 the interval of two years has been preserved. For a short *résumé* of the transactions at the previous meetings the reader is referred to Dr. Warren's address at the last meeting of the Massachusetts Medical Society, which was published in the JOURNAL for June 30th.

Of the success of this last Congress our readers will shortly have an opportunity to form their own estimates, as plans have been taken to secure full accounts from several sources. If the discussions in the Sections were attuned to the key-note given by the president in his address the immediate results must have been extremely valuable, whilst the indirect good influences

flowing from such reunions, not only to medical science, but to all the best interests of civilization, cannot be better portrayed than in the very words of Sir James, when he says:—

"But more clearly in the recollections of the Congress, we may be reminded that in our science there may be, or, rather, there really is, a complete community of interest among men of all nations. On all the questions before us we can differ, discuss, dispute, and stand in earnest rivalry; but all consistently with friendship, all with readiness to wait patiently till more knowledge shall decide which is in the right. Let us resolutely hold to this when we are apart; let our internationality be a clear abiding sentiment, to be, as now, declared and celebrated at appointed times, but never to be forgotten; we may, perhaps, help to gain a new honor for science, if we thus suggest that in many more things, if they were as deeply and dispassionately studied, there might be found the same complete identity of international interests as in ours."

Miscellany.

LETTER FROM LONDON.

LONDON, August 4, 1881.

MR. EDITOR.—Amidst the incessant turmoil of the present session of the International Medical Congress, I think myself fortunate to be able to find the necessary minutes wherein to pen the following disconnected items of news relating to the all-absorbing source of medical interest at the present moment, and congratulate myself on having been able to furnish to you, a week since, many of the more important addresses which are just now from day to day engaging the attention of so many of our most distinguished *confrères* from all parts of the civilized world.

The members of the Congress now amongst us number upwards of twenty-five hundred, at least three fifths of whom are from abroad, and include many of the best known professors from all recognized medical schools, as may be judged from the attached account of the inaugural meeting of the session held yesterday in St. James's Hall.

The official representatives of various governments were present. At eleven o'clock the hall was densely crowded in every part. The appearance upon the platform of some of the most distinguished visitors was the signal for applause, Professor Virchow, of Berlin, coming in for an ovation at the hands of his many admirers. A similar tribute was also paid to Professor Charcot, of Paris, and others. Amongst those present at the commencement of the proceedings were Professor Acland (Oxford), Dr. M. Acosta (Spain), Professor Albernesi (Palermo), Dr. C. Allbutt (Leeds), Professor McCall Anderson (Glasgow), Dr. Fordyce Barker (New York), Dr. Bayer (Brussels), Dr. Lionel S. Beale, Dr. Benedikt (Vienna), Sir J. R. Bennett, Dr. Bouchert (Paris), Professor Cowen Bottini (Milan), Dr. Brandis (Aachen), Dr. Brann (Vienna), Dr. Brinelli (Rome), Professor Businelli (Rome), Dr. Byrd (Illinois), Dr. Chevadaia (Naples), Professor Azzio Casselli (Reggio Emilia), Dr. Lucas Championnière (Paris), Dr. Kraus (Vienna), Sir W. Gull, Cardinal Manning, Sir R. Loyd Lindsay, V. C., M. P., Dr. Chepmell, Canon Barry, the Bishop of London, Pro-

fessor Tyndall, Sir Henry Thompson, Surgeon Major de Chaumont (Netley), Professor Chauveau (Lyons), Mr. Andrew Clark, Dr. Cohen (Hamburg), Sir J. Rose, — Cormack (Paris), Professor Donders (Utrecht), Dr. Matthews Duncan, Professor Esmarch (Kiel), Dr. Austin Flint (New York), Professor Fossagrives (Montpellier), Dr. Galewski (Paris), Dr. W. A. Guy, Dr. Hans von Hebra (Vienna), Mr. Prescott Hewett, Professor Kolliker (Würzburg), Professor Komad (Amsterdam), Dr. C. E. Lyster, Dr. Quain, Professor Pignocco (Palermo), Professor Reverdin (Geneva), Dr. Lydygier (Kulm), Dr. N. Simeinbergh (Rome), Professor Grainger Stewart (Edinburgh), Professor Trelat (Paris), Professor Trendelenburg (Rostock), Professor Erasmus Wilson, Dr. Wunderlich (Stettin), Dr. Wywodzoff (St. Petersburg), Professor Huxley, etc.

The Prince of Wales arrived at twenty-five minutes past eleven. His Royal Highness was received at the doors by Sir William Jenner, Sir William Gull, Sir James Paget, Dr. MacCormac, the general secretary, and other members of the committee, and was conducted by them to the platform, on which his appearance was the signal for prolonged cheering.

It subsequently transpired that the late arrival of His Royal Highness, the Prince of Wales, who is notoriously conspicuous for his almost unexceptional punctuality, was due to his having in vain waited that he might be accompanied by the Crown Prince of Germany. The truth of this rumored explanation was most happily borne out by the Crown Prince of Germany appearing about noon, his arrival in town having been delayed through the shallowness of water near the landing stage at which he disembarked after crossing from the Isle of Wight. His unexpected arrival was the signal for very hearty applause, and he occupied a chair to the left of the President during the remainder of the meeting.

Sir Wm. Jenner, President of Royal College of Physicians, and chairman *ex-officio* of the general committee, took the chair. He said that when our most gracious sovereign the Queen, whose sympathy with all suffering was so true and deep, and whose interest in the advance of medicine and all good works was so widely and well known (cheers) consented to be patroness, and that her likeness should be imprinted on the medal struck in commemoration of this meeting, the success of the Congress as an International Congress was secure, and when, further, his Royal Highness the Prince of Wales announced his willingness to open the Congress, a guarantee was given to the world that their proceedings would be conducted with a gravity and dignity, and their discussions be matters of a nature and importance calculated to support the honor of their profession. (Cheers.)

It would be scarcely courteous to them or congenial to his own feelings were he not to express his idea of the sentiments and aims of those who had collected from all parts of her Majesty's dominions, and from all the great schools of the world (cheers) where the science of medicine was cultivated and advanced, and through which, by means of their pupils, the science of practical medicine and its fruits were diffused throughout the earth. They had been told that commerce was the golden girdle of the world, binding men and nations together by common interests, and with a common aim. But science bound men and nations together with a girdle, the links of which were far

stronger, more durable, and more precious than were the links of the golden girdle of commerce. (Cheers.)

Knowledge was far more precious than gold. Who loved not knowledge? who railed against her beauty? None. With every increase in the world's stock of gold, the metal lost something of its value, while every addition to the world's store of scientific truth added to the value it already had, and was a stepping-stone to the acquisition of more. (Cheers.) Who shall put a limit to knowledge? If this was true of science in general it was true in the highest and widest sense of the science of medicine. (Cheers.)

Commerce was fettered in the supposed or real interests of nations. Commerce, therefore, separated as well as bound men together. Discoveries in other applied sciences than medicine were stimulated by a desire for pecuniary reward, but the discoveries in scientific and applied medicine were open to all the world to use for themselves or to use as foundations for future discoveries. (Cheers.)

The less a physician working to advance medical knowledge was animated by a desire for pecuniary gain, by feelings of personal ambition, or a desire for common applause; the less he mingled his personal wishes with his researches; the less he allowed his hopes and fears to give a bias to the result of his researches; the less he attempted to pervert the answer which Nature gave to the questions he put to her; the more he exhibited in his researches a desire to know the truth for the truth's sake alone; the greater relief his researches afforded to suffering humanity or the more they tended to prevent the recurrence of those sufferings; the more just and generous he showed himself in appreciating the opinions and works of other laborers in the same field with himself, the nearer did he approach to that ideal which they and he had formed of the worthiest workers in their science.

He was sure they all must know men who were thus worthy of fame, and who had approached or reached their own ideal. He had known such; but in the vista of time he looked down and saw one noble form, and he mentioned him because his name was impressed on that great museum which they would have an opportunity of inspecting — Edmund Alexander Parkes. (Cheers.)

To all who knew him he was the ideal scientific worker, and such men not only did good in their generation, but they created amongst those who worked with them, and amongst those who knew them, a desire to tread in their footsteps. (Cheers.)

All medical discoveries were common property, and the richest reward that the discoverers in scientific and practical medicine could have was the consciousness that by the result of their labor and its wide diffusion lives were spared, sufferings were alleviated, and disease was prevented. (Cheers.)

The assembling of this great Congress illustrated the truth of much that he had said. They were here to spread the truths they knew, and to learn from others the truths they could tell. They were here to give their knowledge freely, and to receive from others as freely the knowledge that they could bestow; and in the giving as well as in the receiving they would increase their own store. They were here to thresh out the corn of truth from the worldly chaff in which it was too often enveloped. They were here by their discussions to elicit the truth from the conflicting statements of what was the truth. They were here to meet each

other socially; to remove in that way all prejudices, to promote kindly feeling, to renew old friendships and to lay the foundations of new friendships, and by personal inter-communication to knit more closely the bonds of that professional brotherhood of which they were justly proud. (Loud cheers.)

Mr. Wm. MacCormac, honorary secretary, then read the report of the executive committee, which described the arrangements made for the meetings of the Congress.

Sir J. Risdon Bennett proposed the adoption of the constitution of the Congress, and the acceptance of the list of officers nominated by the committee. He also, in both English and French, bade the delegates welcome.

Professor Donders (Utrecht), president of the Congress of 1879, seconded the motion, which was agreed to by acclamation.

The commemorative medal was then presented to his Royal Highness. Sir James Paget, the newly elected president, having taken the chair, the Prince of Wales, who was loudly cheered on rising, said: "Sir James Paget, your Imperial Highness, and Gentlemen, — I gladly comply with the request that I should be patron of the International Medical Congress of 1881, and amongst my reasons for so doing was my conviction that few things could tend more to the welfare of mankind than that educated men of all nations should from time to time meet together for the promotion of the branches of knowledge to which they devote themselves. (Cheers.)

"The intercourse and mutual esteem of nations have often been advanced by great international exhibitions, and I look back with pleasure to those with which I have been connected. But when congresses are held among those who, in all parts of the world, apply themselves to the study of science and the scientific professions, even greater international benefits may, I think, be confidently anticipated (cheers), more especially in the study of medicine and surgery; for in these the varieties of climate, of national habits, and of social life must give to the practitioners of each nation opportunities of acquiring knowledge which is of considerable value, not to themselves alone, but to those of other countries whom they may meet in Congress. (Cheers.)

"I venture to think, gentlemen, that the executive committee have acted wisely in instituting sections for the discussion of the very wide range of subjects, including both the sciences on which as foundations medical knowledge must rest, as well as many of its most practical applications. I am very happy to see that so great scope will be granted to the discussion of important questions relating to public health, to the care of the sick in hospitals and in the houses of the poor, and to the welfare of the army and navy. (Cheers.)

"The devotion with which members of the medical profession are ready to share in the dangers of climate, of fatigue, and of war, to study every means, not only for the remedy, but for the prevention of disease, deserves the warmest acknowledgment from the public. Gentlemen, I have the great satisfaction of believing when I see this crowded hall that I may already regard the Congress as being very successful in having attracted a number hitherto never equalled of medical men from all parts of this kingdom as well as from every country in Europe, and from the United States of America. (Cheers.)

"The list of officers of the Congress, including, as it

does, the name of nearly every one distinguished in Great Britain in any branch of medical science, shows how heartily the proposal to hold the meetings in London were received; and I think it speaks well for the good feeling of the profession that there was so warm a reception of the proposal from abroad. How cordial it was may be seen in the large number of visitors, which includes a great proportion of those who enjoy the highest reputation in their own countries and throughout the world. I sincerely congratulate the general and reception committees on this good promise of complete success, and I trust at the close of the Congress they will feel that they have been rewarded for the labor they have bestowed upon it. The report which the honorary secretary general has read will have explained how great has been the toil. It will, however, be well repaid, and I am sure that Mr. MacCormac will feel that he is recompensed for even his constant exertions and care if the important science of medicine be promoted, for any addition to the knowledge of medicine must always be followed by an increase to the happiness of mankind. (Cheers.) I declare this Congress now open." (Renewed cheers.)

The president, Sir James Paget, who is a most gifted and skilled orator, then delivered, without a single reference to paper, in a voice which rendered every word agreeably audible to every ear in that vast hall, that perfect address which all may study with pleasure and profit.

The various sections, which number fifteen in all, afterwards met and were constituted. A second general meeting was held in the afternoon, when Professor Virchow (Berlin) delivered an address on the Value of Pathological Experiment. In the evening a *conversazione* was given by the English members of the Congress to the foreign members in South Kensington Museum. This was attended by a vast concourse, and offered a social reunion of the most pleasant character, in which it is estimated that certainly not less than five thousand persons participated.

The almost illimitable objects of interest which the spacious galleries furnish offered but little attraction for the intellectually thirsty multitude who were fully occupied in mentally photographing the features of the many striking personages mingling together. For a considerable portion of the evening the Prince of Wales and the Crown Prince of Germany, accompanied by one of his sons, promenaded through the courts, losing no opportunity of cordially recognizing the numerous medical celebrities with whom he had previously been brought in personal contact.

Hitherto the exceptional, continued perfect weather has lent a most welcome aid to this very successful session of the Congress, and it would seem difficult for any but an experienced student of human nature to believe that aught but applauding criticism would be meted out to the indefatigable organizers of this stupendous business, but the ladies have furnished the exception necessary to prove that general satisfaction which is the rule. For a protest addressed to the general committee of the above Medical Congress, signed by forty-three women legally qualified to practice medicine in their respective countries, is now in the hands of Sir James Paget. It states, amongst other things, that they desire respectfully to request the general committee of the International Medical Congress to reconsider their decision to exclude duly qualified medical women from the meetings of the Congress.

"The Congress in question (the seventh in number) will be the first held in England, and will also, if the present decision of the committee be acted upon, be the first which has not been open on equal terms to all qualified medical practitioners. The question of the admission of women to the medical profession is settled in England, in America, in France, Switzerland, Russia, Italy, and Sweden. There are now the names of twenty-five women on the English Medical Register, all of whom are practicing medicine. Within the last few years a complete Medical School for Women has been established in London, and has been attached to a large general hospital. The students at this school are at present forty in number, and the examinations and degrees of the Irish College of Physicians and of the University of London are open to them. Under these circumstances we submit that whatever opinion may have been held in England, while the admission of women to the medical profession was an open question, to accept a change which has been effected by the combined action of the Legislature, and of the examining medical bodies, is the course most in accordance with the mode in which affairs are usually conducted in England. And we further submit that the interest of medical science will be best served by excluding no one on the ground of sex."

So far as I have heard, in mingling with all in the centre of the Congress, universal praise is acknowledged to have been earned by the executive of the Congress; though of course not unnaturally more than a few feel disappointed at the fact that the Mansion House does not afford accommodation which will enable the lord mayor to entertain more than ten per cent. of the members of the Congress at the banquet which he gives in their honor this evening.

With very few and conspicuous exceptions, the leaders of the profession here are commendably vying with one another in their efforts to extend hospitality to the vast throng of foreign visitors with whom they are now inundated and honored.

The pleasure trips and excursions have been so well selected and arranged that despite their number their attraction renders the would-be participators in them more numerous than can be accommodated, hence all English candidates for invitations have to be submitted to a ballot which must exclude by far the greatest part.

That world-famed British sanitarian, John Simon, yesterday delivered the opening address in the section on State Medicine, and most happily favored the cause of vivisection, prophesying that the sensational legislation which had recently hindered its prosecution in this country must before long be swept away as knowledge and truth became diffused; he quoted with grand effect the experiment with the polluted water which poisoned the mice, demonstrated the potency of infected water in disseminating the poison of cholera, and justly deduced that the few mice were worthily sacrificed to save countless thousands of human lives.

LETTER FROM ST. LOUIS.

MR. EDITOR, — The City Dispensary occupies a very important position in the St. Louis Health Department, and, as its functions are rather different from those of similar institutions in the East, perhaps a description of its work will not be uninteresting to your readers.

Let us premise by stating that imposition is guarded against by requiring applicants to produce a certificate from some responsible person, stating that they are without means to procure treatment elsewhere.

All patients sent to the city hospitals are admitted only by permit from the Dispensary, except in cases of emergency. Thus the Dispensary holds, with regard to the other city institutions, the position of a distributing office. This has formed but a small part of its usefulness, for attendance and medicine are freely furnished those of the sick poor who have homes but are not able to pay for medical attention. There were treated in this way at home during the year ending April 1, 1881, about 9500 patients.

Regular physicians are furnished with blanks which certify that the prescription written on them was not given at any clinic and that the physician receives no pay for his services in the case. These prescriptions are filled at the Dispensary drug store. The number of these prescriptions filled during the last year was 4640.

Those who are able to come to the Dispensary receive treatment there and the number of this class treated during the year was 11,228. The total number of cases, old and new, treated during the year was 20,728.

From these statements the usefulness of the Dispensary system may be easily appreciated and the effect upon the poor of abolishing it imagined. The appropriation for the Dispensary last year was \$17,500, and for the present one only \$9000. On account of this reduction the Health Commissioner has been compelled to reduce the Dispensary force as much as possible and to close entirely the drug department. Prescriptions are still furnished to applicants but no medicines are put up, and no patients are treated at home. By special arrangement, in case of extreme urgency, a limited number of orders — one hundred and fifty per month — are given on a neighboring drug store. The effect of this step is seen in the largely increased number of patients admitted to the city hospitals during the last two months or since the change was made. A free dispensary, supported by the contributions of private citizens, has been opened, and partially meets the necessities of the case. But the various medical colleges are taking steps to inaugurate or enlarge facilities for the treatment of patients in connection with their lectures.

The St. Louis Medical College, especially, will erect a large and conveniently arranged building on the lot adjoining the college, and it is expected to be ready for occupation in the fall. The building will cost \$7000, and will be furnished with all modern conveniences and improvements.

The closure of the City Dispensary will work much hardship to the sick poor during the summer, but it is hoped that its place will be in great measure supplied by the accessory dispensaries which will be in operation by fall.

Very good results have been obtained at the St. Louis City Hospital in sun-stroke cases by the ice-water plan of treatment. Of a total of thirty, treated during the first half of July, 1881, six died, three were much relieved and twenty-one cured. Eighteen of the thirty cases were severe, the patients being unconscious when admitted, notwithstanding preliminary treatment at the Dispensary. Including the six deaths among these eighteen, we have in the most severe cases a death rate of thirty-three and a third per cent.

Flint places the death-rate where the insensibility or coma is prolonged at forty or fifty per cent.

The details of treatment were as follows. Patients on being received, were at once, if the skin was warm and pulse strong, plunged into a bath of ice-cold water and submerged to the neck. Ice water was poured upon the head and chest from a little height. They were left in the bath until the skin felt cool, then removed and put to bed in a cool place and covered, sometimes with a blanket, sometimes with a sheet only. The object in the first being to promote perspiration. It is undecided which is the better. Immediately on being put to bed the patient was given a hypodermic injection of one milligramme of sulphate of atropia. This was repeated in half an hour if reaction was poor or delayed. Cold applications were constantly made to head and chest, and if the temperature rose again the bath was repeated. In the majority of cases this was the only treatment employed. In one case jaborandi was used with good result.

The after treatment was tonic and stimulant in its nature, and varied according to the individual case.

RECENT EFFORTS AT MEDICAL LEGISLATION.

By a recent decision the medical law of California has been declared unconstitutional. The ground on which this decision is rendered is, that the law grants special privileges and is special legislation. This is one of the medical laws on which the advocates of such laws have based their claims for the enacting of similar laws in other States. Whether this decision be sustained or not, it is evident that, in the present state of things, eternal vigilance and eternal expense alone can make or keep such laws in force. The question may well be asked, Is the law worth all it costs? When the people of themselves make such laws, then the matter will be easy; the laws will be executed by the people, as, indeed, they should be. As it now is, the people care little or nothing about the matter, except as one or other of the medical sects stimulate them. Quacks generally have more money to spend in litigation than the regular physicians, and hence, other things being equal, they are the most likely to get the decision they desire.

In Michigan, the law introduced to regulate the practice of medicine has failed to make any considerable progress. In conversation with a member, who is also a doctor and an earnest advocate of the bill, he said that the real difficulty in the matter lay in the fact that large numbers of petitions were presented from the people against the bill, and but few for it. Hence, legislatures said the people do not want the bill and we should not pass it. Clearly, the way to get medical legislation is to convince the legislature that the people want such legislation. How shall this be done? First, the people need such education as shall enable them to see their needs in this direction. How shall the people be educated? Each individual doctor can do very much. Indeed, we think it clear that if each did all he could the people could be educated to this matter in a very short time. Why does not each do his part in this education? Each can best answer this question for himself. Another agency for the education of the people on this matter is found in our boards of health, local and State. In a great variety of ways

these boards have and are educating the people in this matter. The root of the whole difficulty is to be found in a forgetfulness of the foundations of our government and of our laws. We do not always remember that the people are the law-makers, and that every person who can vote is as a law-maker of power. We do not always remember that the people execute their own laws or not, just as they please. Officers or legislatures cannot with impunity refuse to do in the main as the people desire, nor can they long do what the people do not desire. Let us concentrate all our efforts upon the people, if perchance we may accomplish the objects that we seek in a manner that shall be permanent.—*The Detroit Lancet.*

MEDICAL NOTES.

—It is rumored, according to the *Detroit Lancet*, that a new weekly medical journal is to be started in New York. It is stated that twenty-five thousand dollars have been subscribed to this object. It is said that the *Record* does not contain articles of sufficiently high scientific standard. It is already some months since we first heard it suggested that such a project was under consideration.

—The principal members of the International Medical Congress, now in session at London, were present on Saturday at Folkestone at the unveiling by Professor Owen of the statue of Harvey, the discoverer of the circulation of the blood.

—Does Mary cough in the night? Two or three snails boiled in her barley water, or tea water, or whatever she drinks, might be of great service to her; taken in time they have done *wonderful cures*. She must know nothing of it,—they give no manner of taste. It would be best nobody knew it but yourself, and I should imagine six or eight boiled in a quart of water, strained off, and put into a bottle, would be a good way, adding a spoonful or two to every liquid she takes. They must be fresh done every two or three days, otherwise they grow too thick.—*Correspondence of Mrs. Delany, 1758.*

—M. Henry Clozel de Boyer, a French physician, has fallen a victim to diphtheria, contracted in the course of his duties at the Paris Children's Hospital, at the age of twenty-nine. He was one of the most brilliant students of the Paris Faculty, and was assistant physician at the hospital when he contracted the fatal disease.

—The advertisement column of a late issue of the New York *Herald* disclosed the following: "A physician having two diplomas, medical, will sell one upon liberal terms. Address Allopath, *Herald* Up-town Office."

—An interesting experiment is to be tried in West Central Africa, by the members of the Livingstone Inland Mission. Seeds of the different species of cinchona, from the government plantations in India, are to be sent out to them with a view to ascertaining whether it can be successfully cultivated in the mountain valleys of the Congo.

MEETING OF THE BRITISH MEDICAL ASSOCIATION.

PRESIDENT'S ADDRESS.¹

DELIVERED AT THE FORTY-NINTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD IN RYDE, AUGUST 9, 10, 11, AND 12, 1881.

BY BENJAMIN BARROW, F. R. C. S.,

Consulting Surgeon to the Royal Isle of Wight Infirmary.

AFTER introductory remarks, mostly of a local character, the president announced the subject of his address:—

The thought which I gave to this matter (the choice of a subject) has resulted in asking the following questions, and endeavoring to reply thereto, in such a manner as to establish an affirmative to the plea I set up in my proposed questions, and to prove to the public that I have grounds for the plea that the medical profession deserve and expect their sympathy and consideration. To establish this affirmative, I must ask you to permit me to pass in review cursorily the habits of medical men, the manner in which, both in ancient and modern times, they have carried on their manifold duties.

The questions I would ask are these: Are not the duties, the honest and honorable performance of them, such as to command for our profession an equality with, if not preëminence above, every other? If the duties are so performed, are we not entitled to the very highest position in the estimation of the public? Has the profession been so esteemed? If not, what are the causes of such defection? . . .

I am led to this topic, too boldly, perhaps, by an experience of half a century; an experience which induces me to think—having no longer any personal interest in the opinion of the public, save that of my never-dying wish for your welfare, collectively and individually—that I might not uselessly speak to you from the fullness of my heart. My only object is to elevate to the loftiest view your thoughts, and those of the public, in reference to the calling of the medical profession. . . .

I propose to consider my observations under two heads, the secular and the sacred; I shall deal with the secular first,—not that I consider it of primary importance, but because it leads up to the other. The secular I shall treat of under two heads: first, the antiquity of our profession: and, secondly, the work done by men of the past, and that being done by men of the present. . . .

After the consideration of the work done in the past, Mr. Barrow proceeded as follows:—

To the names of those I have placed before you, very many others might be added; but there is one who stands prominent, and who must ever hold one of the first, if not the first place, in our estimation—one who, by self-sacrifice of every description, by an unparalleled perseverance, by an unflinching determination of many years' duration, at last convinced the world that the plague of small-pox was to be combatted by the simple process of vaccination. Has any man, in past times or in the present, approached Edward Jenner as a benefactor to the human race? To his memory stands, in the churchyard of his native place, Berkeley, in Gloucestershire, a monument with the following inscription:—

"Within this tomb hath found a resting place
The great physician of the human race—
Immortal Jenner; whose gigantic mind
Brought life and health to more than half mankind.
Let rescued infancy his worth proclaim,
And hush out blessings on his honored name;
And radiant beauty drop her saddest tear,
For beauty's truest, truest friend lies here."

Greatly may we rejoice that the name of Jenner still shines brightly amongst us, and that one hearing that honored name stands conspicuous as the favored trusted physician of the Royal Lady who, if for no other reasons, calls for our loyal gratitude and never-dying respect, certainly on account of the favor with which Her Majesty always regards our profession, and the deep interest she ever evinces in the sufferings, calamities, and distresses of her subjects. A Jenner, then, is still present with us; and long may he be so, benefiting mankind by his ever ready talented help, and upholding, as he has ever done, and at times under most trying and difficult circumstances, the honor and dignity of our profession. The truth of what I have said has been lately so judiciously and wisely expressed by the Fellows of that learned body, the College of Physicians, that I need say no more.

Can I pass altogether in silence the names of some of our living benefactors? To do so would be doing umbrage to my own feelings, and, I can but believe, to yours also. Men whom we delight to honor, and whose works will live after them.

Do we not number amongst the members of our profession a Hooker, a Watson, a Burrows, and such like? Are not such men as Spenceer Wells, Lister, Thompson, Erasmus Wilson, and others, following in their steps, and doing equally good work for the benefit of mankind? Are they not to be noted as men worthy of special sympathy?

Do we not all respect the name of Paget, who by almost unprecedented labor and perseverance, backed by an unusual genius, has raised the practice of surgery—may I not add of medicine—to be considered, much more universally than was the wont, as scientific and philosophic callings? Then, again, we have another series of medical men, those—and they are almost legion—who have devoted themselves to the rearing of the youthful aspirants to medical honors and renown. No men in our profession deserve more consideration from the public; for upon their teaching depend the future health and happiness of the community, when old men have passed away, and younger and still younger men spring up to grapple with disease and death. I cannot refrain from mentioning one name (although, as I have said, they are legion) prominent amongst teachers. I must run the risk of being called partial when I name Luther Holden, an old and valued friend and a fellow-pupil, as a type of what a teacher should be—one who has devoted his life, energies, and talents of no small order, to the instruction of youth. Much is due to him from the public—much to the many such who have followed and are following the same career.

Let me here allude to medical education generally, and to examinations in particular. The value and high standing of our profession stands not alone upon the actual practice of medicine and surgery, but upon the scientific and philosophical knowledge possessed by medical men. I hope, therefore, that none of those subjects coming under the denominations of physical science or natural history will be laid aside or dispensed with at the examinations; and may these ex-

¹ Reprinted from advance sheets.

aminations before long be under one conjoint board, unanimous in one grand thought — how the best advice and assistance can be secured to suffering humanity.

There are many other grounds upon which the services of medical men merit more than ordinary recognition, both from the State and from the public.

What would our many charities be, of whatsoever character, without the medical man, — without the well-trained student? Without the last named our hospitals could not be worked, however good probationary nurses and lady-superintendents may be; these have, we all know, no mean idea of their own capabilities. The thanks of the profession are, I think, due to those who have of late so nobly, and at so much personal anxiety, withstood the attempts to supplant medical authority in the wards of our hospitals.

The senate claims amongst its members now, in almost every country, many men learned in physic — men who have assisted to legislate for the good of the world at large, and so it has ever been. The halls and theatres of science, both at home and abroad, have been the homes, as it were, of medical men — men ever and anon binding themselves together for the advancement of science in its various branches — men who at the present time in our country make up one fourth of the total number of Fellows of the Royal Society, a society which, we learn, had its origin in 1645. In every society for the advancement of scientific education, medical men stand most prominent, most pronounced in their opinions, sound in their deductions, and persevering in the fulfillment of their preconceived notions and the realization of their fondest hopes.

The work of a medical man is never-ending, there is no fear of his mind becoming vacant for want of occupation, as expressed by a poet: —

"Alone, if occupation is not rest,
A mind quite vacant is a mind distressed."

It is not only by the work he does and which is seen, but by that which is done in secret for the poor and helpless, that the medical man ought to be judged. What profession does so much? Are not medical men daily performing deeds of heroism, facing danger and even death whilst beneficently ministering to suffering humanity, assuaging pain, consoling the bereaved and distressed, both in mind and in body? Can a more striking example of the heroism of a conscientious practitioner be found than in David Lowson, a physician of Huddersfield, who, to relieve the loved babe of an anxious impiring mother, sucks the mucus from the throat in a case of diphtheria? Whether such a course of action is justifiable, unperilling, as this brave man must have known, be heath, it not his life, is a question which can only be settled by the man who performed the deed — it is one of conscience, one of heart. We must all sympathize with David Lowson in the loss of health, and, at the same time, congratulate him upon the recognition of his heroism by Her Gracious Majesty in the presentation of the Albert Medal.

Having, I fear, already tried your patience, I must pass as quickly as possible over that portion of my subject, which consists in a record of the many works which fall to the lot of the medical man; works often, too often, combated by the laity, sometimes with the assistance of men from our own ranks. The work which the medical man has necessarily to carry on is

sufficient to occupy his anxious thoughts, without having his time engaged in refuting charges and upholding in his public capacity those principles which he believes to be right, and which, as a law-abiding subject, he is bound to carry out.

Take, then, the temperance question, through which frequent assaults are made upon us, not only by the public, but by some of our abstaining friends. I respect every man who acts up to his principles; but no man has a right to accuse another of leading his patient to an immoral life because, in his judgment, some moderate stimulant is necessary, either to assist in the cure of disease or to maintain the standard of health. The man, I care not who he is, that scares the public by saying "stimulants are of no use in any class of case or disease" says that of which he can produce no sound philosophic or scientific reasoning as proof; he makes a declamation which I should have been sorry to carry out in my years of practice, and which is no sounder than that made by a man who once said "he cured all cases of cholera with salt." Medical men have been traduced on this subject most unfairly, most unscrupulously. Take away stimulants altogether from the treatment of disease, and I believe you take away one of the chief anchors of medical treatment. I know that stimulants were at one time too freely administered, and they may be so still in rare cases; but who dares to say that the prescriber did not do so conscientiously, believing it was for the benefit of his patient? Beware of giving way to doctrines wholesale, which may be prejudicial to health and dangerous to life.

What shall I say of the antivaccinators, and of the advocates for the suppression of the Contagious Diseases Acts?

My opinion of revaccination I have already indirectly expressed. After years of research, it was found to answer the anticipations of its discoverer; it has borne the test of years, in spite of the criticisms of every class of man and woman, still holding its own valued place as the surest preventive against the most loathsome of diseases, alike destructive of life, faculties, and health. Is it because, ever and anon, we have an outbreak of small-pox, a case of the disease or of death after vaccination, that therefore the operation is a useless one? All men may not be equally cautious in the lymph they use, and I am not sure but that vaccination is one of those minor operations which has not received the amount of attention which it commands.

The law of compulsory vaccination is faulty, in not being strict enough; for no man has a right to violate a law which has been framed for the protection of mankind at large, whatever his own peculiar views may be. The breaking of such laws not only endangers his own life (which the law says he shall not jeopardize), but that of his neighbor. I trust that, if there be legislation, it will be to introduce clauses more stringent than at present exist. I hope there will not be found one man in our ranks who will countenance or support the most unphilosophical, unscientific cry which has ever been raised against a grand discovery.

What shall I say of the anticontagionists? Of these I would speak only one degree less strongly than I have done of the antivaccinationists. Although the test of time has not been very extended, still there is evidence enough to prove that much good has been achieved, and that much disease and distress has been stayed. The argument used that the act legalizes sin

is only one-sided. Because men and women will sin, are we, having a remedy at hand, not to apply it? Are we to leave men and women who sin, and, unrestrained by their sin, destroy the life, the health, and the happiness of a race still unborn, shall we not strive to lessen the chances of "the iniquities of the fathers being visited upon the children," not for one, but for many generations? I grieve that the cry against the Contagious Diseases Act should receive the concurrence of any in our profession; I grieve more particularly because one, an old friend of my own, Dr. Nevins, has taken up this position, a position he strives to maintain by statistical reasonings which do not stand the ordeal of strict investigation.

Another class of oppositionists has still to be dealt with, — the antivivisectionists. I have already told you that the great discovery of the lacteals by Vesalius was made by the vivisection of a dog. What should we have known of the effects of poisons upon the coats of the stomach and intestines? — what of the injury to, and destruction of, the nerve-centres? — what of the treatment of diseases and injuries of bones, if our friends of to-day had sprung up half a century ago? How many more benefits might I not enumerate accruing to the human race from the experiments upon animals, experiments not carried on from curiosity, but from a desire to add to the blessings of health. Scientific men are not such brutes as some would have the world believe; they carry on their researches with every regard to humanity. Let me ask, Will the antivivisectionists give up their fishing and shooting, their delicacies of crimped salmon, lobsters, and crabs? I trow not. The experiments carried on by the man of science are none so painful as the indulgences just described entail upon living animals.

Legislate for the total abolition of vivisection, and one of the levers for increasing our knowledge of the action of new remedies is taken away, and mankind must be the losers. Let me, in concluding this subject, add a paragraph from Darwin's answer to Professor Holmgren, who inquires what Darwin's opinion of vivisection was. He writes: "What improvements in medical practice may be directly attributed to physiological research, is a question which can be discussed only by those physiologists and medical practitioners who have studied the history of these subjects; but, as far as I can learn, the benefits are already great. However this may be, no one, unless he be grossly ignorant of what science has done for mankind, can entertain any doubt of the incalculable benefits which will hereafter be derived from physiology, not only by man, but by the lower orders. Look, for instance, at Pasteur's results in modifying the germs of the most malignant diseases from which, as it so happens, animals will in the first place receive more relief than man. Let it be remembered how many lives and what a fearful amount of suffering have been saved by the knowledge gained of parasitic worms through the experiments of Virchow and others on living animals. In the future, every one will be astonished at the ingratitude shown, at least in England, to these benefactors of mankind. As for myself, permit me to assure you that I honor, and shall always honor, every one who advances the noble science of physiology."

One word more on this subject. What would be the balance of human suffering saved by the knowledge gained by vivisection to that endured by animals who have been the victims of experiments?

Those who know anything of the matter, can but admit that they bear no comparison. Legislation cannot, it must not, be allowed to interfere with free scientific research.

I would commend the foregoing to the company of antivivisectionists at their next drawing-room assembly.

Two other subjects of controversy are still present to my mind — that of lady-doctors and lady-nurses, and the compulsory reporting of infectious cases. Of the last, I would say, that in my opinion no such obligation should be imposed upon the medical man who is the confidential adviser of the infected household, and under no state of things ought he to be forced to reveal the secrets of that house, be they what they may. The burden of such revelation ought to be borne by the occupier of the house; to legislate in this direction would be legitimate, and much good would, I doubt not, follow.

The other subject presents many points of delicacy and difficulty. It is one, as you well know, which has given rise to much controversy; it is open to fair argument and differences of opinion. My own views, I believe, are opposed to those of a considerable number of men whose opinions I value; but I shall nevertheless express my own freely in as few words as possible.

I am not over-squeamish, nor am I over-sensitive; but I almost shudder when I hear of things that ladies now do, or attempt to do; when I hear them talk — the old, the middle-aged, and the young — speaking of things, not *sotto voce*, but boldly and loudly, in society made up of both sexes. One can but blush, and feel that modesty, once inherent in the fairest of God's creation, is fast fading away. You, gentlemen, who know the delicacy of woman's organization, you must know that constitutionally they are unfitted for many of the duties which are required from both doctor and nurse. May not habit, may not the performance of duties which entail long watchings, much exhaustion of mind and body — may they not, will they not, so change that fine organization, that sensitive nature of woman, so as to render her dead to those higher feelings of love and sympathy which now make our homes so happy, so blessed? Will not the strain upon the delicately-nurtured female have a prejudicial effect upon the babe still unborn? Will not England's glory fade without its modest sympathizing women, and its race of stalwart youths and blooming maidens? You now, gentlemen, know my views as to the propriety of ladies becoming doctors or nurses.

Turning now for a moment from civil to military life, are not medical men found equally prominent in other relations to the state? Has not the battle-field told many a tale of heroism, the devotion of medical men, total abnegation of self, sacrifice of life, to save that of others? Has the state adequately rewarded these men — equally brave on land or water — for services rendered? Our profession can boast of many Porters. The one who died but yesterday in Afghanistan lives in the memory of not only those who personally knew him, but of the United Kingdom at large. Neither are we wanting in men such as John Frederick McCrea, lately so graciously decorated by our beloved Queen with the Victoria Cross, for his conspicuous bravery in South Africa, who, in the midst of fire and shot, conveyed a wounded burler to the shelter of a large ant-hill, then sought an ambulance for the relief of the wounded soldier, and, whilst thus engaged, was himself severely injured, but, nothing daunted, continued at his

post, assisting to secure the safety of many more wounded and disabled soldiers. Thus, having done his duty, it was only left for him to dress his own wounds, having no medical brother to assist him. Is not the story an honor to our profession, a glory to our calling?

Let me turn for a few brief moments to the second part of my argument, — the sacred.

If I appear to any of my hearers to dwell unnecessarily upon, as it were, the religious portion, let me ask you to withhold a criticism prejudicial to my observations; for I cannot forget that the profession has been, and is even to this day, by some people accused of being skeptical, and of denying the power of God in creation. I therefore venture humbly to crave your indulgence if I place prominently before you the thoughts which are uppermost in my mind, and which, from my knowledge of medical men, I believe to be present in theirs. As I have previously said, life is a tremendous reality, a serious responsibility. How can this be disputed? Are we not born by and in the image of the Almighty? Perfect in all our parts, endowed with the finest organization, can we doubt that we are born to show forth the glory of God in all our works? Can it be possible that there is one man in our ranks who denies or even doubts the existence of a God?

The study, or even the simple observation, of nature — whether it be the animate or the inanimate — ought to prove to the man of science, or the man of ordinary intellect, that all has been created and is preserved by one Almighty power. If such be the case, is not life a serious responsibility, — may I not say a sacred one; and is not every man, be his calling what it may, bound to exercise his best powers to preserve not only his own life but that of his fellow-men; to do his duty in that station unto which he has been called? Is not our calling a sacred one, being obliged, if we fail not in our duty, to go hither and thither, with or without other recompense, save that of a conscience void of reproach, and the feeling of satisfaction that we have succored a suffering body, thus following in the steps of our Lord and Master? Is it possible to aspire or attain to a higher position than that of being instruments for good, under the guidance of the Great Healer?

That we have a right to aspire to such a height I have no doubt, though some may still be skeptical as to our calling, and may, with like irreverent vigor, as Dryden in verse declares: —

"Better to hunt in fields for health unbought,
Than for the doctor for a nauseous draught;
The wise for cure on exercise depend;
God never made *this* work for man to mend."

Once again. Is not our calling sacred, if we consider our admittance into the domestic circle as a sacred position? Is not our intercourse with families a privilege which must not be abused? Are we not often brought into contact with sin as well as suffering? Are we not intrusted, in confidence, with the cause of suffering, mental as well as bodily? Are we not sometimes, too, the happy medium of reconciliation between those most nearly related? Is it not often in our power to sever those ties which ought to be held the most sacred? If we fulfill properly the trust reposed in us, and treat domestic confidences with that silent judgment which becomes the honorable gentleman, I say confidently that we have the right, looking

at all these calls upon our time and upon our hearts, to proclaim our profession as standing upon the highest grounds.

As the Hippocratic oath set forth how the honorable performance of our professional duties are to be carried out, so, I think, with equal force, do the words of Galen bring home to us the sacred view. If I failed to place before you the religious feelings which formed the predominant feature of his character, I should be doing a great injustice to his memory.

Remember, Galen was brought up in the darkness and polytheism of the pagans; and, living remote from those favored regions over which Christianity had just begun to shed her healing dawn, so fully had Galen's anatomical researches impressed him with the conviction that the grand fabric of the human frame could only be the work of the all-wise, as well as all-powerful and beneficent Being, that he gives vent to the following burst of religious feeling, worthy of a Christian of the nineteenth century, no less than of a pagan of the second. He says: "In writing these books, I compose a true and real hymn to that awful Being who made us all; and, in my opinion, true religion consists not so much in costly sacrifices and fragrant perfumes offered upon his altars, as in a thorough conviction, impressed upon our minds, and an endeavor to produce a similar impression upon the minds of others, of his unerring wisdom, his resistless power, and his all-diffusive goodness. For his having arranged everything in that order and disposition, which are best calculated for its preservation and continuation, and his having condescended to distribute his favors to all his works, is a manifest proof of his goodness, which calls loudly for our hymns and praises. His having found the means necessary for the establishment and preservation of this beautiful order and disposition, is as incontestable a proof of his wisdom as his having done whatever he pleased is of his omnipotence." Many similar examples abound throughout this great man's works, and show that a spirit of genuine piety directed all his thoughts. If the record of these sentiments be true, ought not the accusation of skepticism, even as regards men of old, to vanish from the minds of men? And if, as I contend, the same sentiments are still uppermost in the minds of medical men, ought they to be ever branded by the title of skeptics?

Gentlemen, I have thus endeavored, imperfectly I know, to show why we deserve, and why we ought, to be esteemed and respected of all men. If we are not so, what is the cause? Does it rest in ourselves? I can but fear that to some extent this is the case; we have a censorious public to deal with, and, being in a measure their servants, we cannot throw them off; for, although they are not independent of us, still we are dependent upon them; there is mutual dependence, and there ought to be mutual confidence, — indeed, there *must* be, if we are satisfactorily to do our duty. I advise the man who feels he has lost the confidence of his patient to retire immediately from attendance, — he will no loser by thus showing that he respects his own feelings. I say there must be confidence between the patient and the practitioner. How often is this broken by the innuendoes of one medical man in reference to another? Is there no jealousy, no backbiting between man and man living in close neighborhood? Does that brotherly love exist between men which there ought to be, and which I think the very sacred-

ness of our calling demands? How often do we hear it said, "Mr. A. says Mr. B. has treated me all wrong, not understood my case at all." How glad, alas, is Mr. A. to write a prescription altogether different from what Mr. B. has done! Medical men must differ in opinion as to treatment, and this very difference is the greatest safeguard the public can have; but the difference of opinion and the treatment to be followed need not be made the subject of comment to the patient. The difference ought to be sacred, as between man and man; and I pray that the freer communication now possible, as I have expressed in a former portion of my address, may be the means of reconciling many men hitherto kept apart by only a partial knowledge of each other.

Again, how sadly do medical men arouse the astonishment of the public when called upon to give evidence in judicial inquiries; how diametrically opposed are the opinions advanced, without regard for their own character or for that of the profession! The opinion must be in favor of the side of those on whose behalf each man is called to give evidence, whether it be for or against. Can we be surprised that the laity often accuse us of violating the principles of honor? In no class of cases is this brought more prominently before the public eye than in railway accidents. Is it impossible for medical men, before giving evidence in such cases, to come to some mutual understanding? I trust some way may be found to escape from the scandal by which, under the above circumstances, we are now surrounded. As long as these controversies last, just so long will it be before we attain to that position which we ought to hold in the estimation of the public.

How the backbitings, the jealousies, have existed for so long is marvelous, even in times gone by, in reference to the power, the prosperity, and dignity of one college of learning over another, and which, even to this day, are so far existing as to greatly impede, I fear, the cause of education, and the proof, by one combined examination, as to the fitness of men to be intrusted with the health and lives of their fellow-men. How different this from what Harvey anticipated, as expressed by the last Harveian orator, Dr. Barclay, "how in the early days of the College of Physicians, jealousies crept in, instead of that large-heartedness which Harvey hoped would guide the steps of the Fellows of the College."

Can we be surprised, then, that the public, being critical, should look doubtfully upon our profession, and refuse us that meed of just sympathy and position which we certainly deserve? Let us hope that a great future is in store for all our colleges and seats of learning, and that they may be pregnant of great results, both as regards the advance of science and the eligibility of those who are destined to go about doing good, following in the steps of their Great Master. . . .

Permit me now to draw my conclusions from what I have ventured (I hope without offense to any individual, present or absent) to place before you. I trust, moreover, that the sum and substance of my observations may have the effect, which I greatly desire, of clearing away some of the clouds which surround the lay public, and that my observations may bring those who have hitherto looked upon our profession as a necessary evil, rather than a good, to believe at any rate that, although we may differ individually as to treatment of disease, we are not antagonistic collectively; that our feelings towards each other are broth-

erly; and that in the performance of our duty toward our patients and to the public we are actuated by true and honest motives, and the most honorable intentions. Gentlemen, a review of what I have already said cannot fail, I am bold enough to hope, to prove that our profession merits the highest consideration from the world at large, and that it stands upon the topmost pinnacle of fame.

Gentlemen, only a few words more, and I have done. Many thanks for your patient attention to my sayings, which I fear have been dull and uninteresting. I trust that no word has fallen from my lips offensive to any one here. I have spoken from the fullness of my heart, with but one desire, namely, that the high position in which our profession already stands may be maintained and increased, and secure for you, individually and collectively, that respect which, if honestly, honorably, and perseveringly carried on, your calling merits.

In conclusion, I would venture to say, pray each morning before you commence your day's labor, which labor cannot be attended but by much anxiety, and at times by disappointment and sorrow, mingled happily, however, by some bright spots; pray, I say, that you may be blessed by that Divine help which can alone sustain you and carry you successfully through labors and anxieties of no mean order, and when evening comes pour forth thanksgivings that strength and knowledge have been given you, to do your duty, in mitigating to some extent the sufferings of your fellow-men. These are the only sure and safe steps to a happy life and a prosperous career. . . .

ADDRESS IN MEDICINE,

BEFORE THE BRITISH MEDICAL ASSOCIATION AT ITS LATE MEETING AT RYDE.¹

BY JOHN SYER BRISTOWE, M. D.

MR. PRESIDENT AND GENTLEMEN, — There are few more interesting and curious studies than the history of medicine. Taking its origin in the very dawn of human existence, not in the instincts which lead men to obey the dictates of nature, but in the sense of rebellion which the pains and penalties she inflicts engenders, it was cradled in the credulity and superstition which are the first fruits of thought struggling for independence. It is not surprising, therefore, that in the earlier ages, when their origin and nature seemed alike mysterious, diseases should be attributed to the influence of stars and comets, to the malignity of demons, to the wrath of deities; and that their alleviation or cure should be sought in amulets and charms, in sacrifices and prayers. Nor is it surprising that in later times, when the knowledge of disease had advanced, and the influence of drugs had become recognized, a belief came to prevail that for every morbid evil which nature permitted to afflict mankind she had provided an antidote. Nor, perhaps, is it to be wondered at that, even at the present time, in this enlightened age, not merely among the lowly and the ignorant, but amongst the noble, the learned, and even the scientific, credulity and superstition in relation to the common enemy of mankind — disease — should still widely prevail; that diseases should still be attributed to supernatural causes, and to the spleen of

¹ Reprinted from advance sheets.

an offended deity; that still amulets and charms, sacrifices and prayers, should be included in the popular *materia medica*; or that the belief should still be entertained (for which no scientific basis whatever exists) that diseases, which are the necessary correlatives of mortality, are mere puzzles, designed by nature for the exercise of ingenuity in the discovery of remedies, which she has industriously hidden in the eternal rocks, and in the living things which people the face of the earth or clothe it with verdure.

It has been largely held, and is doubtless still believed, that the position of medicine as a science is a discredit to the age in which we live; and it may be freely admitted that, while the arts and sciences generally have been making rapid strides, medicine, in its primary and chief object — namely, the cure of diseases, — has made but scanty and doubtful progress. But those who hold this view have given little real thought to the subject. In no small measure they are persons who have no acquaintance whatever with medicines who judge of it by its failure to accomplish ends which are probably impossible of accomplishment, and who are themselves to a great extent credulous as to the efficacy of measures and of remedies whose use is an outrage on common sense. But largely they are persons who base their judgment on a false comparison of the progress of medicine with that of the exact sciences, and of the natural sciences on which alone scientific medicine is built. They forget that mathematics and geometry are (difficult, no doubt, but) comparatively simple sciences, which men may cultivate in the closet, apart from life and nature, and which the ancients, therefore, were as well able to investigate with success as ourselves. They forget that the physical sciences and chemistry, which deal only with the simple forces of nature and unliving matter, have only within the last hundred years made those gigantic strides which have raised them from the depths of empiricism and quackery to the marvelous position which they now hold among our intellectual and effective possessions. They forget that the natural sciences, the sciences which deal with living nature, — namely, botany, zoölogy, anatomy, physiology, and pathology, — though long cultivated fitly and to little purpose, have only of late years made systematic progress; and that it is mainly within the present century that anatomy, physiology, and pathology have risen into the dignity of sciences, and have worked a very revolution in our knowledge and estimate of life, in both its normal and its abnormal conditions — of health and disease. And, lastly, they forget that the scientific treatment of disease can only be based on a scientific knowledge of the structure and functions of the healthy body, on a scientific knowledge of the causes and processes of diseases in it, and on a scientific study of the methods and means by which those morbid causes and processes can be prevented, counteracted, or destroyed, and that such a study is only now becoming possible.

I confess that to me it seems altogether Utopian and unreasonable to expect either that diseases shall ever be banished from the earth, or that even diseases generally shall become curable by therapeutical or any other treatment. All living things are foredoomed to die; and the more complicated their structure, and the higher and more multitarian their functions, the more liable are they to suffer from those changes of structure and derangements of functions which constitute essential elements of disease. Moreover, the causes of

disease abound, and form, as much as we ourselves do, an integral part of the economy of nature. Why should they cease to exist and act and we survive? Again, assuming the persistence of diseases, what grounds of reason or experience have we to justify the belief that for every disease an antidote or cure will sooner or later be discovered? The history of medicine raises no such hope. There is nothing in the nature of diseases themselves to render such a consummation probable. The immortality of mortal life is neither conceivable nor to be desired. Still less is there any reasonable or sufficient basis for the assumption that diseases, differing absolutely from one another in their nature, and depending on causes which have no mutual connection and act upon the system in various and independent ways, should all be amenable to treatment in accordance with one simple theory of therapeutics.

I am not presuming to question the benefits that medicine has conferred upon mankind; still less to deny the promise of greater things to come. I know that, in the past, many glimpses of therapeutical truth have from time to time been caught; and that veins of bright ore have here and there been discovered in the dreary waste of empiricism and charlatanism. I see that, at the present time, pathology and the investigation of the causes of disease are throwing fresh and unexpected light on the nature of diseases, and are leading us into new lines of successful practice, especially in relation to their prevention. And I cannot doubt that as our knowledge of the processes and causes of disease extends, so will our power to prevent disease acquire a wider range, and attain more certainty of operation; and that here, more than in the direct treatment of disease, our future successes will be found. But neither can I doubt that the progress of this and cognate sciences, aided by well-devised experiments and careful observation of diseases, will lead both to the discovery of new remedies and to the more successful use of those we already employ.

I shall not pursue the subject of the potentialities of medicine, fascinating though it be. It is in the vagaries, and not in the science, of medicine, that for this hour my interest centres. I am not going to investigate or explain how it is that systems of medical treatment of disease have originated, have played their part in the drama of human life, have given place to others, and yet (though henceforth discredited in the eyes of man) have left behind them relics which are still embodied in the therapeutical practice and theories of the present day. It is easy, however, to understand how, on the one hand, the vague beliefs, speculations, and errors — the growth of ages — should have gradually acquired form, and blended into creeds; and how, on the other hand, ingenious and self-reliant minds, speculating on the mysteries of nature, should have gradually evolved out of their inner consciousness elaborate systems in explanation, with nothing but their ingenuity to commend them. Thus it was that, in accordance with the first alternative, the Doctrine of Signatures gradually arose; thus it was that, in accordance with the second, Galen elaborated his celebrated hypothesis respecting the virtues and operations of medicines. It seems marvelous that such fantastic fictions as these were should ever have developed in the minds of men, and for ages have been accepted as true, and adopted in practice, not only by the ignorant and thoughtless, but by physicians of conspicuous ability and eminence.

But, gentlemen, the age of credulity is not yet passed; and doubtless, as long as humanity strives to unravel the secrets of nature, and to explain her actions, there will be men, and men, too, of cultivated intellects, who, in the search after truth, will be led astray by will-o'-the-wisps, and who will end by making idols of the vain pigments of their minds, by pulling down and worshipping the golden images they have themselves set up. Such a man, it seems to me, was Hahnemann, the notorious founder of homeopathy. It is of him, and of the sect he founded, that I propose to speak to-day.

Hahnemann became a medical man from choice, and pursued his studies in respectable schools and under fairly eminent teachers. He acquired some credit as a practitioner while yet young, though probably not more credit than many of his contemporaries, and many who have preceded and many who have followed him, have also obtained, whose names, nevertheless, have never emerged from obscurity. But he appears to have given his mind mainly to the study of chemistry, botany, and therapeutics; and certainly there is no evidence from his writings, or any other source, that the study of disease itself had any interest for him. Though he had friends, he seems, like most physicians, to have failed in early life to make his profession lucrative; and either for this reason, or, as some assert, because he became dissatisfied with the methods and systems of treating disease then in vogue, he retired for a time from practice, and gave himself up to his favorite studies, and to the translation of French and English works relating to them into his mother tongue. However this may be, many will sympathize with him now, as many doubtless would have sympathized with him then, in the dissatisfaction which, about this period, he undoubtedly felt with the chaotic state of therapeutical theory and practice at that time prevalent, and with the aspirations that sprung up within him to make order out of confusion, to discover some intelligible relation between therapeutic agents and morbid processes, to systematize the curative treatment of disease. And many even of those who dissent most widely from his conclusions will still, I think, admire the tenacity, the energy, and the sublime bigotry he displayed in the development of that system of which he was at once the creator and the apostle.

His system took its origin in those scholastic views of the nature of disease, of the nature of remedies, and of the influence of remedies on disease, which more or less have influenced the theory and practice of medicine from the earliest ages down to the present day. Looking upon diseases, not as what they are, but as mere assemblages of symptoms; and upon remedies, not as what they are, but as agents specially given by Providence with the one hand to cure the evils which he had scattered broadcast with the other; and, guided by certain superficial relationships, easily observed, between the effects of certain morbid conditions and the effects of certain drugs, it was not unnatural for observant and thoughtful men to speculate on the hidden laws which might be supposed to underlie such relationships, and to generalize. Thus, some perceiving that constipation of the bowels was overcome by purgatives, diarrhoea by astringents, and that hemorrhages were arrested by styptics, thought that in such facts they recognized the general therapeutical law that all diseases should be treated by their opposites (*contraria contrariis curantur*); some noticing that coma was

relieved by purgatives (that is, that affections of the head were favorably influenced by remedies acting on the bowels); that affections of internal organs were benefited by counter-irritants and such like phenomena, originated the theory that disease was curable by remedies which were unlike in operation to themselves, the theory to which the term *allopathy* was given by Hahnemann; and, again, some observing that diarrhoea was often relieved by purgatives, that constipation was often best treated by remedies having a tendency to restrain the action of the bowels, that inflammation of the skin was frequently cured by the application of remedies which themselves tended to irritate the skin, were pioneers in the alleged discovery which Hahnemann proclaimed to the world in the legend *Similia similibus curantur*, and under the name of *homeopathy*.

It is clear, if one looks only at some of the coarser phenomena of disease and effects of remedies, there is some warrant in fact for each of these three theories of treatment, but none for regarding one or other of them as of universal applicability. It is clear, too, that any one arguing back from such facts as these to the hidden workings of diseases and remedies within the corporeal frame, and at the same time shutting his eyes to the phenomena of life as they exist actually, might bring himself to the belief that there were three modes corresponding to those enumerated above, and three only, in which remedial agents could act upon the processes of disease: namely, one by acting in opposition to them (*antipathy*), one by acting in accordance with them (*homeopathy*), and one by acting heterogeneously to them (*allopathy*). But it is difficult to understand how any one who has followed in any degree the advances, during the present century, of the natural sciences, and especially of those which relate to the structure and functions of the human body in health and disease, and to the aetiology of disease, can see any plausibility in such speculations, any provisional hypothesis even, such as sometimes aids the advance of science — any meaning whatever in them.

Now Hahnemann's special views of disease and its treatment originated, and how they underwent gradual development, until they found exact expression in his *Organon*, the bible of homeopathy, I shall not attempt to discuss. The *Organon* itself, however, is a remarkable work, very interesting also, and very entertaining; for it comprises not only the quintessence of his labors, but reveals the character of the man, as in a mirror, with all his strength and all his weakness, all his wisdom and all his folly.

He was a physician who had a supreme contempt for pathology, and on the whole for aetiology. He inveighs over and over again against the absurdity of those who endeavor to discover, in morbid phenomena within the body, an explanation of the symptoms which persons who are ill present. He says: "We may well conceive that every malady implies a change in the interior of the organism, but this change can only be surmised obscurely and fallaciously from the symptoms; it can never be recognized infallibly in its complete reality. The invisible changes wrought by the malady within the organism, and the changes perceptible to our senses (that is to say, in some of the symptoms), together form a complete image of the malady; but that image is only visible in its entirety to the eye of the Creator. It is the totality of the symptoms which alone constitute the part of it accessible to the doctors; but it is likewise in the totality of

the symptoms that we find everything that it is needful to know in order to cure." To Hahnemann it is a matter of no moment whether ascites depends on cirrhosis of the liver, or tubercle of the peritonæum; whether an attack of constipation and colic arises from lead-poisoning or from a cancerous stricture; whether a paralytic seizure is the outcome of hysteria, or is due to some material lesion of the brain. In each case, to him, what is the condition of things within is an idle speculation: the symptoms for which the patient complains comprise all that the medical man need know; and to treat those according to the true laws of homœopathy is to cure the disease. But he goes further; for, not satisfied with stigmatizing all pathological investigations as mere pedantry and foolishness, he actually objects to all attempts on the part of systematic writers and practical physicians to distinguish and classify diseases. Speaking of pathology in the past, he says: "It created arbitrarily the object of cure — namely, the malady. Men decided authoritatively what are the number of diseases, what their form, and what their genera. Good God," says he, "the infinity of diseases which nature excites in man, exposed as he is to so many different influences, under conditions never to be determined beforehand, and infinitely varied, is reduced to such an extent by pathology that there remains only a handful of them furnished according to its whim." Elsewhere he observes: "We may also pass over in silence the fact that persons have tried to reduce the number of maladies — those infinitely varied deviations from the state of health — to a limited list of denominations, and to give the definite descriptions (which vary, nevertheless, according to different pathological views), in order to afford a ready indication of medical treatment for each form of illness that is artificially defined in therapeutics." And again he says, in reference to the causes of disease (which he regards as innumerable): "Thence come an infinite number of heterogeneous diseases, which are so different from one another that (to speak strictly) any case of illness appears only once, and (if we except the few diseases which originate in a miasm) always of the same kind, or which arise from the same cause, every man who becomes affected suffers from a special malady, to which no specific name can be given, and which has never existed in the same manner as in the present case, in the particular individual and under existing circumstances, and will never be reproduced in exactly the same form."

From these quotations we may fairly gather what his views of the nature of disease were. In the first place, he admitted that diseases originated in causes; but these causes were innumerable, and operated in innumerable combinations, and hence (excepting in the cases of miasmatic affection, and some few specific fevers which he could not deny the existence of, and enumerated) were barren subjects of investigation, and as indications for treatment worthless, if not misleading. Indeed, in one place, speaking of intestinal worms (which we regard as causes of disease), he denies that they are causes of disease at all; and says that when they irritate, they irritate simply from the fact that they are themselves suffering, together with their host, of some malady under which their host labors; professing (in accordance with his preconceived views) to imagine some hidden cause, rather than to acknowledge that, as the cause which offered itself in a visible and tangible form to his senses. For him, I should

think, preventive medicine, which deals specially with the cause of disease, and has been successful only in proportion to its knowledge of them, would have been a delusion and a snare. In the second place, pathology, and more especially morbid anatomy, had no meaning for him. All the laborious investigations conducted in our dead-houses, which we fondly imagine add to our knowledge of disease, and to which (in association with clinical study) we attribute most of the advances that have been made in medicine of late years — such as the differentiation of kidney diseases, the recognition of suprarenal medicine, the discovery of the condition known as embolism, the exact recognition of the nature of tumors, the discoveries which have been made in regard to the diseases of the nervous system — would be looked upon by him with contempt. For what, in the third place, have such investigations and such knowledge to do with diseases as he understood them. His diseases, as I have shown, were, with a few exceptions, simply groups of symptoms — mosaics of what the component pieces admitted of endless rearrangement. Intermittent fever constituted one of the cases in which he recognized the operation of a definite cause; but, notwithstanding this, intermittent fevers were themselves innumerable, and each case that came before him was an independent disease.

I do not wish to misinterpret his views. He recognizes, I admit, the existence of morbid causes; but he seems to liken them to the impulse which propels a ball, and to think that with their initial impulse all this specific influence ceases. Nor does he deny the existence of pathological changes in the interior of the body; but he says that we cannot detect them, that, as a matter of fact, they are correlated with the symptoms which patients present, and together with this are common manifestations of the same disease, and that in the symptoms alone we have a sufficient indication of the nature of the disease and of the treatment to be adopted for its cure.

Of course, in all this there is much that is true, and much that is specious. Were it not so his theories would long ago have been abandoned; for it is the mixture of truth and verisimilitude with error that gives error currency. But how much of wild speculation, how much of absolute ignorance of the matters which he proposes to teach, how much obstinate shutting of his senses to the truths of nature.

Hahnemann's views of the nature of disease were doubtless subservient to his views of the curative operation of drugs. And it is on his therapeutical views, if on anything, that his reputation must depend. He says, in his introduction, "All human maladies have up to the present time been cured, not in accordance with reasonings founded on nature and experience, but in accordance with hypotheses arbitrarily devised, such as (amongst others) the law of palliatives, *contraria contrariis*. Yet it was from this opposite side that the true method of cure was arrived at. It is based on the following principle: to cure gently, promptly, certainly, and durably, we must select, in every case of sickness, a medicine which produces of itself a similar affection to that which it is intended to cure. No one up to the present time has taught this homœopathic method; no one has yet practiced it." And he goes on to add that all the maladies that had heretofore been cured had been cured by homœopathic remedies. Let us see exactly what the nature of his teaching is. He seems to start from the fascinating belief that all symptoms of disease,

and therefore from his point of view all disease, are curable. He seems also to have adopted the belief (already adverted to) that for all diseases nature has provided a cure. And he holds that the only proper and efficient cure for any assemblage of symptoms is a remedy which is capable itself of causing in a healthy person an identical assemblage of symptoms.

Stated generally, his views are as follows: the innumerable diseases which afflict mankind, and which arise out of natural causes, consist, for the purposes of the physician, of groups of symptoms; the innumerable remedial agents which exist in nature, locked up in the animal and vegetable kingdoms, and in the inorganic world, are themselves the causes of a parallel basis of artificial diseases, which again, for the purpose of the therapist, consist of groups of symptoms; in order to cure any natural disease that may come before us it is necessary to administer that particular remedial agent which is capable of producing identical symptoms with it, and of course this must be given in a suitable dose, for if in too minute a dose it leaves a residuum of the original disease uncured; if in too large a dose it cures the disease, but induces after-effects of its own; and, further, inasmuch as we are not yet acquainted with the specific virtues of all remedies, and inasmuch, therefore, as for a large number of diseases the most suitable homœopathic remedy has not yet been discovered, we must in such a case select a remedy the effect of which approximates to the symptoms of the disease, by which means we shall cure a certain area, so to speak, of the primary disease, but we shall leave a new disease behind, compounded of the as yet uncured symptoms of the old disease, and the supernumerary symptoms due to the drug itself, which new disease must be treated *de novo* on homœopathic principles. How curious, how ingenious, how interesting the whole thing is! How excellent, if true! And has it not the simplicity of truth in it? The entire range of diseases, the entire range of therapeutics converted into Chinese puzzles; the phenomena of diseases and the effect of drugs upon them treated as algebraical equations! It is impossible to conceive of any physician working daily by the bedside of patients, and in the dead-house, and seeing diseases as they are, forming such a system, except as a joke. It could only have been, as in fact it was, the serious work of a visionary who had thrown off the trammels of fact, and, allowing his imagination to run riot, mistook its fantastic figments for a revelation from heaven.

That Hahnemann believed in himself and in the absolute truth of all that he taught is beyond dispute. He was a prophet, not only to his followers, but in his own eyes. All other systems of therapeutics but his were folly, and all who pursued them were fools. That he had training, and ability, and the power of reasoning, is abundantly clear. He saw through the prevalent therapeutical absurdities and impositions of the day: he laughed to scorn the complicated and loathsome nostrums which, even at that time, disgraced the pharmacopœias; and he exposed with no little skill and success the emptiness and worthlessness of most of the therapeutical systems which then and theretofore had prevailed in the medical schools; and then he invents and proclaims a system of his own at least as empty and as worthless as any that had gone before. In this, I suppose, there is nothing very strange: for it is only the broadest intellects (and his was an essentially narrow one) which are capable of treating the offspring of

their own brains with the same impartiality they manifest in other cases. But, under the circumstances, it will be interesting to consider, however briefly, the character of the therapeutical facts and arguments which he himself alleges in support of his doctrines, and the methods of investigation which he taught and practiced.

In the first place, in order to prove the truth of his assertion, that all cures which had heretofore been effected by drugs were effected in virtue of their homœopathic action, he ransacks the writings of his predecessors; and, while omitting to quote (probably, in his opinion, as absolutely worthless) any of the multitude of recorded cases in which cures had been attributed to remedies which could in no sense be regarded as homœopathic, he quotes a number of at least equally worthless cases, in which he thinks he recognizes the curative influence of unconsciously applied homœopathic treatment. The following are two of his quotations: "The English sweating disease, at its beginning more deadly than the plague itself, and which, according to Willis, destroyed ninety-nine patients out of every hundred, could not be overcome until doctors had learnt to treat the sick with sudorific remedies; from that moment, as Sennebert remarks, few persons died of it." Again: "Albus informs us that the high temperature of an acute fever, with 130 beats of the pulse in a minute, was much reduced by a hot bath of 100 degrees of Fahrenheit, and that the beats of the pulse consequently sank to 110." I have no doubt the quotations he gives here are essentially accurate. But surely it is well known that all the older physicians claimed to have discovered, towards the close of any epidemic fever, no matter what its virulence, the true method of curing it, which discovery coincided in time with the rational disappearance of the disease. Many men have thought and declared that they had cured plague and cholera and typhus with similar circumstances by remedies, some of which may even have been homœopathic. Does any one believe that such asserted cures of these incurable diseases ever took place? Is there any sufficient reason to admit that the sweating disease was ever more amenable to treatment than this, or that it was, in fact, ever cured by sudorifics, or any other remedies? And as regards the case of the reduction of temperature by the bath, Hahnemann fails entirely to see that the patient's temperature was much higher than that of the bath; that the bath was relatively cold to him; that it relieved him by reducing his temperature; and that the treatment was, not only not homœopathic, but essentially anti-pathic; that the case, if it proves anything, proves the efficiency of one of those very methods against which he pours out the vials of his wrath. These are simply samples. I could run through the whole series of them, and show that, while a large number of them were merely loose and untrustworthy statements of supposed facts, nearly all of them prove nothing whatever, to my unbiased mind, in response to those homœopathic principles which they are assumed to support. Naturally, the recently introduced non-relation of cow-pox, as a preventive of variola, is adduced by him as a homœopathic remedy against the latter disease. He fails to observe that it is preventive alone; and that, so far from acting as a cure of small-pox, it aborts when applied to a variolous patient, while his disease runs its course wholly uninfluenced by it.

In the second place, as regards his own homœopathic observations. These, as given in his *Organon*, are not

very numerous. For the most part, he there lays down the law oracularly, and quotes the more or less questionable and loose statements of other authors in support of his opinions. There are some two or three observations, however, apparently his own, or at any rate confirmed by his own experience, which are really interesting. He speaks, as I have before pointed out, of intermittent pains as being innumerable, and derides the blind pathology which makes of these one disease, and proceeds: "Pathology feigns this in order to give pleasure to her dear sister Therapeutics, who, excepting antimony and sal ammoniac, has, as a rule, no other remedy against intermittent pains than quinine, with which it treats them according to a fixed method, as if they were all identical! It is true," he continues, "that these pains can be suppressed by enormous doses of quinine, that is to say, that their periodical recurrence is overcome by it; but those who are affected with intermittents for which this remedy is unsuitable are not cured by it, but remain continually ill, and worse than they were before. And this is what the vulgar art of medicine calls a cure!" He regards quinine, and mentions it elsewhere, as a homeopathic remedy for ague attended with certain groups of systems. Homeopathic, forsooth! when the most striking therapeutical fact concerning quinine is that it lowers temperatures; while the most striking clinical feature of ague is the extraordinary rise of temperature which attends its paroxysmal attacks. But fancy ague, which (Hahnemann notwithstanding) is in all its forms identically the same disease, being homeopathic to quinine in one case, and allopathic or antipathic in another; being in one case curable by quinine administered in infinitesimal quantities, and in another aggravated by the same remedy in large doses. I do not know what the present views of homeopathic practitioners may be as to the relations of quinine and ague; but I appeal to every one of experience besides as to whether ague ever succumbs to the use of infinitesimal doses of quinine; and whether, in the large majority of cases, it does not yield, with no ill consequence (due to the drug), to quinine in large quantities? What is the experience of our Indian colleagues in this matter? Again, he speaks over and over again of itch, a disease with which he seems to have been familiar, and which he assumes to be an affection pervading the whole organism, but attended, as small-pox is, with a rash; and in reference to it, he insists upon the folly of endeavoring to cure this skin-disease by local applications, a procedure which he says has the effect of aggravating the constitutional disorder; and teaches that the disease is only to be cured by the internal administration of sulphur in homeopathic doses. Now, it is pretty certain that Hahnemann did not very clearly distinguish itch from many other forms of cutaneous eruption; still, many of his cases of itch were true itch, no doubt. But what can practical men think of the insight into diseases, of the power of observation, of that man who discovers that to destroy the local phenomena of itch is to aggravate the patient's illness; that itch itself is even curable by any internal remedy whatever. No doubt he was not aware that itch is due to the burrowing of parasites in the skin; but if he had been it would have made no difference to him; for he would have argued of them, and of their relation to itch, as I have already shown that he argues of intestinal parasites, and the symptoms of disease which are usually attributed to their presence.

But, in the third place, before medicines can be employed homœopathically, their collective effect must of course be ascertained and tabulated; and, before cases of disease can be treated homœopathically, their symptoms must all be accurately determined and tabulated; in order that the appropriate, or at any rate the most appropriate, remedy may be selected for each. We cannot, therefore, quarrel with Hahnemann for requiring that drugs shall be carefully tested or proved, and that cases shall be carefully and accurately recorded. But what does he mean by proving of medicine, and what by testing of cases? Most men accustomed to scientific investigations would say that, in order to determine the precise potential characteristics of any unknown agency, it should be interrogated and cross-examined and tested from all points of view; that, if a drug, its chemical properties should be determined, and its action on the living and on the dead, in health and disease, should be exhaustively ascertained. That is not Hahnemann's notion at all. Drugs being, in his view, agencies which impart disease, must be tested only on the healthy body, in order to determine, in accordance with homœopathic requirements, what natural diseases their effects simulate. And the method of procedure is, that the experimenter, and those who act under his directions, shall take regulated doses of the drugs they wish to examine, and thus note in each case accurately every phenomenon which develops itself during some period, determined more or less arbitrarily, after the reception of the drug. The results to the uneducated eye look, perhaps, fair and reasonable. But we must admit the truth of the homœopathic view of the relations between medicines and diseases before we can admit the special value of investigations conducted only on the healthy body; and, as regards the method of investigation which he teaches, can anything be better calculated to promote self-deception. Think of the innumerable phenomena which a hypochondriacal old man, a youthful enthusiast in experimental research, or a credulous lecturer would find under such circumstances arising from inconceivable doses of the most inert substances — the itching at this joint, the aching at that, the variation in the pulse, the watering of the eyes, the noise in the ears, the muscular startings, the eructations, the swellings in the bowels, and many other matters of the same kind. What pictures of the mimicry of disease may be thus produced and varied *ad infinitum*; of what innumerable pictures of the kind (comprising here and there doubtless accurate and valuable observations) is the homœopathic literature on the processes of drugs made up. The recording of cases, according to Hahnemann's directions, is of a piece with the proving of medicines. He tells us to listen carefully to the account the patient gives of himself, to hear all that the friends and others about the patient say concerning him, and to note down everything accurately, and in tabular form. You are not to interrupt. And then, when the recitals have been completed, you are permitted to ask certain questions, the character of which he carefully specifies. But you are never to suggest anything to the patient; and you are never, so far as I can make out, to cross-examine him. Imagine the picture of her condition that a garrulous old lady would give under such conditions. Imagine the innumerable histories of diseases you would get in which everything accessory and unimportant would be recorded, and everything really distinctive and important for diagnosis and treatment,

as we understand them, omitted. I am not prepared to say the method is a wrong one from the homœopathic point of view, in which diseases as objects of medical treatment are regarded only as an assemblage of symptoms, and in which the interconnection of symptoms is comparatively unimportant. But what a caricature of scientific case-taking it reveals to us. What an unpractical condition of mind it manifests in him who elaborated it. What light it throws on his curious incapacity for exact scientific observation. How like his method is to that of an industrious newly-appointed clinical clerk. How utterly opposed to the procedure of the experienced scientific physician.

Perhaps the most astonishing feature of homœopathy, as Hahnemann bequeathed it to us, is his hypothesis of infinitesimal doses. He discovered, from the results of his experiments and practice, that, when once the true homœopathic remedy for any disease, or rather collection of symptoms, had been ascertained, it was needful, in order at the same time to secure the full effect of the drug and to obviate any ill effects it might leave of its use, to reduce the doses of it to an inconceivable minuteness. The millionth, the billionth, the trillionth of a grain were gigantic quantities compared with some of those which finally he found it best to administer. It has been calculated that a drop from the lake of Geneva, through the waters of which a single grain of medicine had been diffused, would contain one of his ordinary doses; and that a drop from a mass of water similarly treated long enough to filtrate the whole solar system, would contain as large a dose as is furnished by some of these extreme attenuations! When we laugh at these infinitesimal doses, the retort is often made that we ourselves use small doses; and calculations are flung at us, showing how excessively minute must be the amount of any potent drug administered by the stomach which reaches the organ wherein it induces specific effects, and how absolutely inappreciable must be the bulk of odorous particles which not only affect the sense of smell, but even provoke coryza, sickness, and faintness. Wherein, then, is the absurdity of the Hahnemannic dosage? But this is not a retort that Hahnemann would have made; and, indeed, it is one that could only rise to the lips of degenerate followers of his. It is not the amount of any drug which reaches any one part of the organism which is in question, but the amount of it which has to be administered for a dose. And it cannot be denied that the smallest doses employed by us, even such as Dr. Ringer recommends, are gross indeed compared with those of Hahnemann. Where we give a drop or the hundredth part of a grain he would have given the millionth or the billionth part of that quantity, at the very most, and probably millions of billions less than that. Moreover, the principles underlying the two cases are wholly dissimilar.

The limit in the efficacy of infinitesimal doses involved the violation of his theory. It was, indeed, I think, the natural outcome of it. The mystical powers, which for him resided in drugs, bore no quantitative relation to the ponderable element with which they were associated. They are contained in them much as the genius in the fisherman's story in the Arabian Nights was contained in the leaden bottle which was fished up from the bottom of the sea. It is easy, then, if not inevitable, for him to imagine that the power of drugs became more and more developed, in proportion

as the grosser matters which environed the drug were removed. It is easy, too, from another point of view, for a vaguely mathematical mind like his (which had already dealt with diseases as if they were algebraical equations) to conceive that, just as mathematics becomes a more and more potent instrument, according as the encumbrances of arithmetical and ordinary algebraical præcipe are thrown aside, and one comes to deal, as in the differential calculus, with the mere ratios which survive in quantities which have been reduced to zero, so medicine would become a more and more potent art, according as the coarser portions of drugs and of diseases are eliminated from consideration, and we have only to do with the relations or ratios (if I may so express it) between drugs attenuated to nothing, and diseases reduced to mere groups of intangible subjective phenomena! One may, I think, follow Hahnemann's lines of thought; one may trace, I think, without much difficulty, the steps by which his system acquired its full development, and culminated at length in the doctrine of infinitesimal doses. The author of homœopathy himself carried homœopathy to its logical consequences! and was there ever a more amazing *reductio ad absurdum*!

I intended, gentlemen, when I first thought of preparing the address, to devote no inconsiderable portion of it to the consideration of some of the modern developments of homœopathy. But the time at my disposal is insufficient for that purpose; and I shall content myself with only one or two remarks upon the subject. It is only natural that amongst the many followers of Hahnemann, some, though believing in the essential truth and value of his teachings, have ventured, within certain limits, to think for themselves; and that hence sub-sects, or a tending to the formation of sub-sects, should have arisen. It is hardly possible, for example, that all homœopaths, who have received a medical education, should accept Hahnemann's views of the nature of diseases; and many at the present day do, I believe, acquiesce in the teachings of modern pathology. It is hardly possible, again, that every homœopath should believe fully in the efficacy of the infinitely little doses which Hahnemann contended were the most efficacious, or should believe in the potential effect of the shakings of his preparations, to which, in fact, he largely attributed the development of curative energy in them; hence the change with some is much larger than Hahnemann could have sanctioned. Then, again, was it to be expected that any thinking man could admit that remedies cured because they produced identical effects with them (and, indeed, unless one assumes that remedies act like Pharaoh's lean kine, and then die of a surfeit, it is difficult, to say the least, to imagine Hahnemann's process of cure in progress); and hence has arisen a hypothesis with respect to the influence of minute doses in the cure of diseases, which is fully as ingenious as Hahnemann's own, and is probably just as true, but which has the theoretical disadvantage for homœopaths of converting homœopathy into antipathy! It is to the effect that all medicines have opposite effects, according as they are given in large or small doses, and that when, as the consequence of proving on the healthy person, a drug is found to excite the symptoms of a disease it cures that disease by its opposition to it when given in small doses. I shall not stop to consider the propriety or plausibility of these and other like innovations in orthodox homœopathy; and I leave those who advocate them to reconcile them as best they may with

the teachings of their founder; neither shall I quarrel with the homœopaths who choose to maintain that these only represent successive stages in the progressive development of homœopathy. To me, I confess, they seem in direct contravention of homœopathic principles, and fraught with ultimate disaster to the homœopathic cause.

It is perhaps the most difficult thing in the whole practice of medicine to determine in disease whether the drugs which we are giving are directly influencing it for good. This difficulty is specially great when, as sometimes happens even to ourselves, we are, from ignorance of the essential nature of the disease we are treating, or from failure to form an accurate diagnosis, compelled to treat, as Hahnemann only treated, groups of symptoms. It is true that even the most accurate observers constantly deceive themselves. It was mainly by treating diseases simply in groups of symptoms that Hahnemann deceived himself from first to last. And it is mainly thus that homœopathic practitioners continue to deceive themselves down to the present time. When they can show that, by remedies acting homœopathically, they can cure habitually definite diseases, which by other means we cure uncertainly, or fail to cure altogether; that they can cut short, or render less fatal than they are, the fevers that tend to run a definite course, it will be time for us to make homœopathy a serious study. For tetanus, for epilepsy, for hydrophobia, typical homœopathic remedies exist. Was ever tetanus, epilepsy, or hydrophobia cured by homœopathy? They profess to ward off and to cure scarlet fever, by what they hold to be its homœopathic antagonist, belladonna. Is scarlet fever less frequent or less fatal in the families of homœopathy than amongst the general population? What evidence is there which we can accept, that any internal inflammation, any internal growth, any specific fever, has ever been cured, or even ameliorated, by homœopathic remedies? Of course affirmative assertions will be made, of course statistical evidence will be forthcoming. But mere assertions — and mere statistics are simply talanted assertions — are not evidence which a man professing scientific caution would accept in such a case? Nevertheless, did homœopathy possess one tittle of the curative power that Hahnemann claimed for it it must long before now have commanded the homage of even its most inveterate enemies. For it must be recollected that the claims of homœopathy are not in equality of results with those of orthodox medicine, but that they are to alleviate and cure diseases over which we have little or no control, to relieve where we hurt, to save life where we kill.

So far, gentlemen, I have discoursed only on homœopathy as a science and an art; I wish to add a few words on homœopaths as men, and as members of our common profession.

That a very strong feeling of hostility should have arisen early between orthodox practitioners and homœopaths, is not to be wondered at, when we consider, on the one hand, the annoyance and intolerance which Hahnemann displayed, at any rate in his writings, and on the other hand the contempt which experienced physicians felt and freely expressed for him and his whimsical doctrines. Nor is it to be wondered at that the variance should still be maintained; for homœopathy is still a protest against the best traditions of orthodox medical medicine; and there is a natural tendency among us still to look upon homœopathic

practitioners as knaves or fools, but surely this view is a wholly untenable one.

That all homœopaths are honest men, is more than I would venture to repeat, but that in large proportion they are honest is entirely beyond dispute. It is quite impossible that a large sect should have arisen, homœopathic schools and hospitals have been established, periodicals devoted to homœopathic medicine be maintained, and a whole literature in relation to it have been created, if it were all merely to support a conscious imposture. No, gentlemen; the whole history of the movement and its present position are amply sufficient to prove that those, at any rate, who take the intellectual lead in it are men who believe in the doctrines they profess, and in their mission; and who practice their profession with as much honesty of purpose, and with as much confidence in their power to benefit their patients, as we do. That all homœopathic practitioners are men of ability and education, it would be absurd to maintain; but it is absolutely certain that many men of ability and learning are contained within their ranks. If you care to dive into homœopathic literature, you will find in it (however much you may differ from the views therein inculcated) plenty of literary ability; and I have perused many papers by homœopaths on philosophical and other subjects enumerated with homœopathy, which have proved the authors to be men of thought and culture, and from which I have derived pleasure and profit. Again, I will not pretend that even a considerable proportion of homœopaths are deeply versed in the medical sciences; yet they have all been educated in orthodox schools of medicine, and have passed the examinations of recognized licensing boards; so that it must be allowed that they have acquired sufficient knowledge to qualify themselves for practice, and some among them possess high medical attainments.

But it may be replied, If these men are honest and educated, and at the same time duly qualified practitioners in medicine, how can they believe and how can they practice such a palpable imposition as homœopathy? Well, gentlemen, it is very difficult to account for the beliefs and vagaries of the human intellect. It is only occasionally that our convictions are the result of conscious reasoning. For the most part they arise in the mind, and take possession of it, we know not how or why; and our reasonings in regard to them (if we reason at all) are merely special pleadings prompted by the very convictions they seem to us to determine — in other words, they are not the foundations of our beliefs at all, but exhalations from them. It is not surprising, therefore, that, even on matters of supreme importance, irreconcilable differences of opinion prevail, yea, even amongst men of high integrity and cultivated intellect. And if we desire to live broad and unselfish lives, we must be slow to condemn all those who entertain convictions which to us seem foolish or mischievous, and logically untenable, or to refuse to cooperate with them.

There are few, even of the best among us, who have not weak points in intellect or character. And it would be deplorable, indeed, if, for example, those of us who look at spiritualism as one of the grossest follies of the times in which we live, were to scout the distinguished chemists and the great writers who devoutly believe in it; or were to refuse to do homage to the conspicuous abilities and high character of a great judge, because, throwing off the judicial impar-

tiality which befits a judge, and acting under the influence of prejudice, emotion, and ignorance, he has made himself the leader of all the hysterical sentimentalism of the day in a crusade against experimental physiology in the land of Harvey and of Hunter! The remarks just made apply especially to beliefs in relation to those matters which are incapable of exact scientific proof, and in which the feelings are largely involved — pre-eminently, therefore, to religion, to politics, and to medicine.

I ask you, gentlemen, to forbear with me, if I push my argument to the logical conclusion, and venture now to express an opinion which is opposed to the opinion which many, perhaps most, of you entertain. I do not ask you to agree with it; still less do I ask you to accept it. But I ask you to consider it; and I am content to believe that, if it be just, it will ultimately prevail. It is that, when homœopaths are honest, and well-informed, and legally qualified practitioners of medicine, they should be dealt with as if they were honest and well-informed and qualified. I shall not discuss the question whether we can, with propriety or with benefit to our patients, meet homœopaths in consultation. I could, however, I think, adduce strong reasons in favor of the morality of acting thus, and for the belief that good to the patient would generally ensue under such circumstances. I shall not consider at length whether the dignity of the profession would be compromised by habitual dealing with homœopaths. But I may observe that it is more conducive to the maintenance of true dignity to treat with respect and consideration, and as if they were honest, those whose opinions differ from ours, than to make broad our phylacteries and enlarge the borders of our garments, and wrap ourselves up, in regard to them, in Pharisaic pride. I appeal, gentlemen, in support of my contention, to other considerations. It has been held that to break down the barriers that at present separate us from homœopaths would be to allow the poison of quackery to leaven the mass of orthodox medicine. But who that has any trust in his profession, any scientific instinct, any faith in the ultimate triumph of truth, can entertain any such fear? All the best physicians of old times, all the greatest names in medicine of the present day, are with us; and we know that as a body we are honest seekers after truth. What have we to fear from homœopathy? Bigots are made martyrs by persecution; false sects acquire form and momentum and importance mainly through the opposition they provoke. When persecution ceases would-be martyrs sink into insignificance; in the absence of the stimulus of active opposition sects tend to undergo disintegration and to disappear. The rise and spread of homœopathy have been largely due to the strong antagonism it has evoked from the schools of orthodox medicine, and to the isolation which has thus been imposed on its disciples. If false, as we believe it to be, its doom will be sealed when active antagonism and enforced isolation no longer raise it into fictitious importance. At any rate, breadth of view, and liberality of conduct, are the fitting characteristics of men of science.

COMMON DANGERS IN DWELLING-HOUSES.

MESSRS. MAGUIRE AND SOX, of Dublin, who have had large experience in the examination of houses, say in a recent circular: —

"In endeavoring to awaken public attention to the importance of sanitary reform, we here enumerate thirty of the dangers to health which we most frequently detect in our sanitary examination of houses. Any one of these defects, by admitting foul air, constitutes a real danger to health; but, in the large majority of houses, many of these defects may be found existing together, and in some houses they may nearly all be found rendering those dwellings pestilential. (1.) Common built drains under houses; large built drains under or near mansions. (2.) Pipe-drains with leaking joints, or broken, laid under houses, saturating the basement with sewage. (3.) Pipe-drains laid under houses without sufficient fall, or with fall the wrong way. (4.) Drains of every kind, without proper intercepting traps, admitting foul air from sewers or cess-pools. (5.) Drains of every description, without a constant free current of fresh air through them. (6.) Rat burrows from built drains or sewers undermining flags and floors, and admitting foul air to houses. (7.) Rat burrows worked alongside perfect pipe-drain from street sewers, and into houses. (8.) Defective connections between soil or waste-pipes and sewers, admitting foul air to houses. (9.) Soil-pipes passing through interior of house, under almost any circumstances. (10.) Soil-pipes inside or outside houses without any or sufficient ventilation. (11.) Defective water-closet apparatus. (12.) Water-closet cisterns with overflows joined to soil-pipe or drain. (13.) Safe-trays under closets, connected to soil-pipes or drain. (14.) Two or more water-closets or sinks on same soil-pipe, untrapping each other when used. (15.) Sink overflow-pipes joined to soil-pipes untrapped, or with trap liable to untrap. (16.) Water-supplies to sinks taken from water-closet or other contaminated cisterns, and used by careless servants to fill bedroom carafes for drinking. (17.) House cisterns and tanks with overflows direct into soil-pipes or drains. (18.) Traps of every description without ample ventilation to guard them. (19.) Scullery sinks connected direct to drains, admitting foul air to houses, not only through traps, but through joints of brickwork all round, as shown by our smoke test. (20.) Bell-traps, with loose covers, on scullery sinks connected to drains. (21.) Gullies or traps in sculleries, laundries, larders, etc., connected to drains, usually dry and untrapped. (22.) Rain-pipes used as ventilators to drains delivering foul air near bedroom windows, or under eaves or roofs. (23.) Ashpits near larders and pantries; ashpits liable to soak foul moisture through house-walls. (24.) Defects of drainage and rat burrows from neighbors' houses. (25.) Water-tanks in areas, near ashpits or sculleries, and with overflows direct to drains. (26.) Washhand basins in dressing-rooms, connected directly in any way to drains or soil-pipes. (27.) Water-closet cisterns in return rooms, frequently under bedroom or parlor floors, perhaps with overflow direct to drain. (Sixteen years ago the writer thoughtlessly used a room of this kind, and was attacked with typhoid.) (28.) Cess-pools near houses, and cess-pools or defective drains near wells. (29.) Neighbors' drains crossing under houses or joining drains. (30.) Drinking-water defects, and all impurities likely to contaminate milk, meat, or food of any kind."

The list is a long one, but it is only too true that such dangers are common in dwelling-houses, and are often unrecognized until repeated illness has called attention to them. — *British Medical Journal*.

Recent Literature.

A Medico-Legal Treatise on Malpractice, Medical Evidence, and Insanity, Comprising the Elements of Medical Jurisprudence. By JOHN A. ELWELL, M. D., Member of the Cleveland Bar, etc., etc. Fourth edition, revised and enlarged. New York: Baker, Voorhis & Co., 1881. Pp. 600.

If one may be permitted to judge by the enthusiastic statements in the preface to this volume, as well as by the very complimentary testimonials which the author and his publishers have thought it well to introduce not only in the pages usually devoted to such sweetmeats, but also in extraordinary and questionable relations as notes at the end of many of the chapters, this work in its previous editions has been received with remarkable favor. It would not, however, require microscopic vision on the part of the independent and discriminating critic to discover certain defects in the book, both in its literary construction and in its special character as a medico-legal treatise. Many grammatical errors mar its pages, inconsequential and obscure sentences disturb the sensitive reader's equanimity, and a few obviously erroneous statements appear in connection with the citation of adjudicated cases, and indicate that the revision has not been as careful and thorough as the title-page hints. Notwithstanding the author's assertion that "as in former editions, so in this, the knife has been relentlessly applied to all surplus brush, that symmetry and healthy fruit-bearing may be the result," one finds many places where the "brush" was overlooked or has grown with great rapidity since the last relentless pruning was performed, while in other parts (especially in the closing chapters) the application of the knife has left bare poles only, with scarcely enough foliage for decency's sake; in either case, the inequality of the work has made the search for the healthy fruit a matter of some difficulty.

As a medico-legal treatise, the book seems to us to have come somewhat short of fulfilling its destiny. The author having practiced medicine several years, and having then abandoned that "noble profession" (as he calls it repeatedly) to devote his attention to the law, believed himself in a position "to promote the great ends of science and justice by endeavoring to embody in a concise, complete, and comprehensive work all the settled principles and known authorities as well as the result of his own thought and experience," upon certain departments of medical jurisprudence. In thus avowedly attempting to serve at once the needs of both medicine and law, he has inevitably found himself cramped at times by the character of his authority. One is occasionally in doubt concerning the intent of this medico-legal Janus, whether the doctor or the lawyer is addressed chiefly, and it is reassuring to come upon such admonitions as these at the end of some of the chapters: "The foregoing remarks are designed more particularly for the legal profession" (page 54); and, again, "These general suggestions are designed especially for medical men" (page 272). It would save the reader's time if these bits of advice had been placed at the beginning rather than at the end of the sections to which they relate. But perhaps the trouble in this connection lies not so much in the author as in the plan of the book. It is impossible in the compass of six hundred pages to incorporate all

the principles of forensic medicine which shall successfully guide the practitioners of both professions in their service of public morality. The lawyer will not be assisted greatly in his practice by an intimate knowledge of the intricacies of toxicology or the details of pathological anatomy; nor will the medical witness obtain much aid and comfort from any preliminary study of "adjudicated" cases in preparing himself to encounter safely the pitfalls, and sloughs, and quicksands of the court-room. *Ne sutor ultra crepidam.* Let the man of law have the benefit of the medico-legal precedents so fully set forth in the book before us, and when occasion arises let him meet the medical witness courteously and in good faith for a complete and intelligent preparatory rehearsal and mastery of the medical elements then specially involved in the case at issue; and let the medical witness, on his part, insisting that he is none the less a physician and none the more a lawyer because he is at the service of the courts, shun the technicalities of the law, assured that they will not assist him much when he is on the witness-stand, and that he cannot go far wrong if he respects the requirements of his oath.

As a matter of fact, the work under review is essentially a legal rather than a medico-legal treatise, and will serve the distinguished author's brethren of the bar better than his former fellows in medicine; the language of the book has a pervasive legal flavor; it is particularly rich in the citation of cases which have passed before the highest courts in England and America; and even its external appearance, its tawny leather and its red and black labels, establish its claim to the congenial company of Kent and Roscoe and Bouvier. The physician will do better to retain on his shelves his Taylor, and Guy, and Casper, and Beck, writers to whom our author repeatedly refers, with more condescension than grace, as "elementary."

It is not to be understood that we regard Professor Elwell's work as of slight merit. In spite of its deficiencies there is very much in it that is of exceeding interest and value. The opening chapters on malpractice and medical evidence, upon which the author appears to have devoted most of his attention, are elaborated with great care, and the section on insanity is very complete, and will well repay the reader's perusal.

The closing chapter discusses the coroner's office, and contains the familiar refrain about the decadence of that once worshipful adjunct to the judiciary. Some excellent arguments are adduced for the regeneration of the coroner's function. It does not appear to have come to the author's knowledge that Massachusetts long ago solved the problem satisfactorily; it is possible that before another edition of his work is prepared for the press he will have learned the details of the inquest method here in vogue, and will esteem them worthy of mention in a foot-note at the least. D.

The Compend of Anatomy, for Use in the Dissecting Room and in Preparing for Examinations. By JOHN B. ROBERTS, M. D. Second Edition. Philadelphia: C. C. Roberts & Co. 1881.

The fact that the first edition of this little work was exhausted in a few months shows that it meets a want. If we remember rightly we spoke of it as very good of its kind, for we do not like compends. The second edition is revised and enlarged.

Medical and Surgical Journal.

THURSDAY, AUGUST 25, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

CARBONIC OXIDE: DANGERS TO HEALTH FROM CAST-IRON FURNACES AND STOVES.

In a recent number of the National Board of Health Bulletin Professor Ira Remsen reports the results of an investigation lately undertaken by him for the purpose of determining, if possible, whether carbonic oxide is a constituent of the air of rooms heated by cast-iron stoves and hot-air furnaces. The conclusions to which he arrives, in so far as they relate to the dangers to be apprehended from the passage of carbonic oxide through heated cast iron, are interesting, since they differ from those which have been reached by other investigators and generally accepted as final. It is the prevailing belief that the injurious effects produced by breathing the air of rooms heated by cast-iron stoves and hot-air furnaces are due chiefly to the inhalation of carbonic oxide, and that the presence of this gas is explained partially by the fact that cast iron, at a red heat, takes it up from anthracite coal and permits its passage directly through its substance.

MM. St. Claire Deville and Troost first stated, as the result of experiments undertaken by them to determine whether cast-iron stoves were objectionable or not, that carbonic oxide may and does pass through cast iron heated to redness.

A little later the subject was thoroughly investigated by a committee appointed by the French Academy. The conclusion reached by this committee was that cast-iron stoves, as soon as their temperature reaches dark-red heat, cause the escape of not inconsiderable quantities of carbonic oxide. Although these conclusions have been pretty generally accepted as true, still different results have been obtained by some of the later investigators. H. Vogel was unable to find any evidence of carbonic oxide in the air of certain school-houses in Berlin, although by the method employed by him he could with certainty detect 2.5 parts of the gas in 1000 parts of air. J. Gottschalk in 1877 examined the air of certain school-houses in Leipzig; he found no evidence of carbonic oxide, although by the method which he employed he claimed to be able to detect 0.22 parts of the gas in 1000 parts of air. In 1878 S. Wolffhügel made some experiments with a cast-iron stove, on the side of which was a box covering one square decimetre of cast-iron that could easily be heated to redness. The air drawn from this box was then examined by means of Vogel's blood test. In all his experiments the results were negative.

It was in view of the uncertainty connected with the subject, and its importance, that it seemed to Professor Remsen desirable to undertake a new investigation, which he did at the request of the National Board of Health. In his report he calls attention to the work of previous investigators, criticises the methods employed by them, and gives his reasons for doubting the conclusions arrived at by Deville and Troost, and by the French commission. His first step in the investigation proper was to carefully study the methods which had been used, in all the earlier experiments for the detection of carbonic oxide, and he is convinced that Hempel's method is the best one now at our command for this purpose. Hempel's method, which is a modification of Vogel's blood test, consists in allowing mice to breathe the air under examination, killing the mice, and examining the diluted blood with the spectroscope. By this method he could with certainty detect four parts of carbonic oxide in ten thousand parts of air.

The next step in his investigation was to apply the method to the examination of the air of such buildings as seemed to be the most suspicious. The air in a comparatively large number of rooms was examined. The result of the examination was that carbonic oxide was not detected in a single case, and the conclusion is justified that in rooms heated by cast-iron stoves and furnaces there is not present in the immediate vicinity of the hot-air flues as much as 0.04 per cent. of carbonic oxide.

Experiments were also made with cast-iron stoves for the purpose of determining whether carbonic oxide passes through cast iron heated to redness or not. All these experiments gave negative results, and showed that under apparently the most favorable conditions not as much as 0.04 per cent. of carbonic oxide passes through heated cast iron.

These results are in accordance with those reached by Vogel, by Gottschalk, and by Wolffhügel, and at variance with those obtained by the French commission; and Professor Remsen thinks it desirable that the work of the commission should be repeated, account being taken of the influence of the possible sources of error to which he calls attention in his report.

It would seem, then, that the reference to carbonic oxide as a source of danger by reason of its passage through cast iron heated to a high temperature should be modified to some extent. A question arises whether carbonic oxide in smaller quantities than those which can be detected by Hempel's method may not be present. As there seems to be no reliable method for detecting smaller quantities the question must, for the present, remain unanswered. Professor Remsen thinks the hypothesis perhaps justifiable that carbonic oxide is present in quantities less than 0.04 per cent.

It is also a question whether such small quantities of the gas are injurious to health or not. Vogel and Wolffhügel think that as long as the air does not contain 2.5 parts carbonic oxide in 1000 it may be regarded as uninjurious. Von Fodor, on the other hand, thinks that even 0.25 parts of the gas in 1000

parts of air must be regarded as injurious to health, basing his opinion upon the results of experiments upon animals, in connection with the fact shown by Friedburg that man is more sensitive to the action of carbonic oxide than animals.

In case it is shown that carbonic oxide is present, but in quantities too small to prove injurious, it remains to be discovered what the real cause of the bad effects of furnace air is. All these questions are important, and it is desirable that the whole subject be further investigated. It should be borne in mind, however, in considering the investigations just referred to, that the escape of carbonic oxide, when there is an insufficiency in the draught or when the heating apparatus is mismanaged, is not denied.

Miscellany.

LETTER FROM LONDON: INTERNATIONAL MEDICAL CONGRESS.

PROFESSOR HUXLEY'S ADDRESS. — DISTRIBUTION OF COMMEMORATIVE MEDALS. — CONCLUDING EXERCISES, ETC., ETC.

London, August 9, 1881.

THIS day is the last of the seventh session of the International Medical Congress, which has been fortunate in enjoying perfect weather during its assembly, with the single exception of a few hours yesterday afternoon. Last night the Royal College of Surgeons of England invited to a *conversazione* all the members of the Congress, who thus enjoyed a rare and grand opportunity of intellectual intercourse and entertainment amongst their many-tongued confrères and the endless collection furnished in the world-famed Hunterian Museum. Immediately within the entrance there stood in line the president, vice-presidents, and council of the college, ready to greet each comer. Thus all had an opportunity of shaking by the hand many a distinguished surgeon who had previously been known to them only by reputation.

The concluding meetings of the International Medical Congress were held in St. James's Great Hall to-day, Sir James Paget occupying the chair. Sectional meetings were held in the morning, and in the afternoon Professor Huxley addressed the sixth general meeting on *The Connection of the Biological Sciences with Medicine*. The great body of theoretical and practical knowledge, he said, which had been accumulated by the labors of some eighty generations, since the dawn of scientific thought in Europe, has no collective English name to which an objection may not be raised, and he used the term *medicine*, as that which is least likely to be misunderstood, though, as every one knows, the name is commonly applied, in a narrower sense, to one of the chief divisions of the totality of medical science. Taken in this broad sense, "*medicine*" not merely denotes a kind of knowledge, but it comprehends the various applications of that knowledge to the alleviation of the sufferings, the repair of the injuries, and the conservation of the health of living beings. In fact, the practical aspect of medicine so far dominates over every other, that the "*healing art*" is one of its most widely received synonyms. It is so difficult to think of in doing otherwise than as something which is necessarily connected with curative

treatment, that we are apt to forget that there must be and is such a thing as a pure science of medicine, — a "*pathology*" which has no more subservience to practical ends than has zoology or botany. The logical connection between this purely scientific doctrine of disease, or pathology, and ordinary biology, is easily traced. Living matter is characterized by its innate tendency to exhibit a definite series of the morphological and physiological phenomena, which remain the same, within narrow limits, for each kind of living thing. They furnish the normal and typical characters of the species, and as such they are the subject-matter of ordinary biology. Outside the range of these conditions the normal course of the cycle of vital phenomena is disturbed; abnormal structure makes its appearance, or the proper character and mutual adjustment of the functions cease to be preserved. The extent and the importance of these deviations from the typical life may vary indefinitely. They may have no noticeable influence on the general well-being of the economy, or they may favor it. On the other hand, they may be of such a nature as to impede the activities of the organism, or even to involve its destruction. All that can be said is, that whatever change of structure or function is hurtful belongs to pathology. Hence it is obvious that pathology is a branch of biology; it is the morphology, physiology, the distribution, the ætiology of abnormal life.

However obvious this conclusion may be now, it was nowise apparent in the infancy of medicine. For it is a peculiarity of the physical sciences that they are independent in proportion as they are imperfect, and it is only as they advance that the bonds which actually unite them all become apparent. Thanks to the intimate alliance of morphology with medicine, the natural history of disease has, at the present day, attained a high degree of perfection. Accurate regional anatomy has rendered practicable the exploration of the most hidden parts of the organism, and the determination during life of morbid changes in them; anatomical and histological post-mortem investigations have supplied physicians with a clear basis on which to rest the classification of diseases, and with unerring tests of the accuracy or inaccuracy of their diagnoses. If men could but be satisfied with pure knowledge, the extreme precision with which in these days a sufferer may be told what is happening and what is likely to happen, even in the most recondite portions of his bodily frame, should be as satisfactory to the patient as it is to the scientific pathologist who gives him the information. But Professor Huxley expressed his fear that it is not; and even the practicing physician, while in nowise underestimating the regulative value of accurate diagnosis, must often lament that so much of his knowledge rather prevents him from doing wrong than helps him to do right. Disease is the perturbation of the normal activities of a living body, and it is and must remain unintelligible so long as we are ignorant of the nature of these normal activities. In other words, there could be no real science of pathology until the science of physiology had reached a degree of perfection unattained, and, indeed, unattainable, until quite recent times. Modern, contrasted with ancient, physiology, offers physical explanations of vital phenomena, or frankly confesses that it has none to offer.

So far as the professor knows, the first person to give expression to this view was René Descartes. The body, he holds, is a machine of the nature of an army,

not that of a watch or of a hydraulic apparatus. Of this army each cell is a soldier, an organ is a brigade, the central nervous system headquarters and field telegraph, the alimentary and circulatory system the commissariat. Losses are made good by recruits born in camp, and the life of the individual is a campaign, conducted successfully for a number of years, but with certain defeat in the long run. The efficacy of an army at any given moment depends on the health of the individual soldier, and on the perfection of the machinery by which he is led and brought into action at the proper time; and, therefore, if the analogy holds good, there can be only two kinds of diseases, the one dependent on abnormal states of the physiological units, the other on perturbation of their coördinating and alimentative machinery. Hence the establishment of the cell theory in normal biology was swiftly followed by a cellular "pathology" as its logical counterpart; and henceforward Professor Huxley regards the connection of medicine with the biological sciences as clearly defined. Pure pathology, he sets forth, is that branch of biology which defines the particular perturbation of cell life, or of the coördinating machinery, or of both, on which the phenomena of disease depend. But the last form of the battle between the animistic and the physical views of life is seen in the contention whether the physical analysis of vital phenomena can be carried beyond this or not. There are some to whom living protoplasm is a substance, even such as Harvey conceived the blood to be, "*Summa cum providentia et intellecta in finem certum agens, quasi ratiocinio quodam*," and who look with as little favor as Bichat did upon any attempt to apply the principles of growth, metabolism, and contractility. They stand, said the speaker, on the ancient ways; only in accordance with that progress towards democracy which a great political writer has declared to be the fatal characteristic of modern times. They substitute a republic formed by a few billion of "animalæ" for the monarchy of the all-pervading "anima." Others, on the contrary, supported by a robust faith in the universal applicability of the principles laid down by Descartes, and seeing that the actions called "vital" are, so far as we have any means of knowing, nothing but changes of place of particles of matter, look to molecular physics to achieve the analysis of the living protoplasm itself into a molecular mechanism. If there is any truth in the received doctrines of physics, that contrast between living and inert matter, on which Bichat lays so much stress, does not exist. In nature nothing is at rest, nothing is amorphous; the simplest particle of "brute matter" is a vast aggregate of molecular mechanisms, performing complicated movements of immense rapidity, and sensitively adjusting themselves to every change in the surrounding world. Living matter differs from other matter in degree and kind; the microcosm repeats the macrocosm, and one chain of causation connects the nebulous original of suns and planetary systems with the protoplasmic foundation of life and organizations. From this point of view pathology, Professor Huxley said in his closing observations, is the analogue of the theory of perturbations in astronomy; and therapeutics resolves itself into the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy. And, as pathology bases itself upon normal physiology, so therapeutics rests upon pharmacology, which is, strictly

speaking, a part of the great biological topic of the influence of conditions on the living organism, and has no scientific foundation apart from physiology. It appears to me that there is no more hopeful indication of the progress of medicine towards the ideas of Descartes than is to be derived from a comparison of the state of pharmacology at the present day with that which existed forty years ago. If we consider the knowledge positively acquired in this short time of the *modus operandi* of curare, of atropia, of bromide of potassium, of phosphorus, of physostigmin, of veratria, of cascra, of strychnia, there surely can be no ground for doubting that sooner or later the pharmacologist will supply the physician with the means of affecting in any desired sense the functions of any physiological element of the body. It will, in short, become possible to introduce into the economy a molecular mechanism, which like a very cunningly contrived torpedo shall find its way to some particular group of living elements and cause an explosion among them, and leave the rest untouched. The search for the explanation of diseased states in modified cell life, the discovery of the important part played by parasitic organisms in the aetiology of disease, the elucidation of the action of medicaments by the methods and the data of experimental physiology, appear to me to be the greatest steps which have ever been made towards the establishment of medicine on a scientific basis. I need hardly say they could not have been made except for the advance of normal biology. There can be no question, then, as to the nature or the value of the connection between medicine and the biological sciences. There can be no doubt that the future of pathology and of therapeutics, and therefore that of practical medicine, depend upon the extent to which those who occupy themselves with these subjects are trained in the methods and impregnated with the fundamental truths of biology. And I venture to suggest that the collected sagacity of this Congress could occupy itself with no more important question than this. How is medical education to be arranged so that without entangling the student in those details of the systematist which are valueless to him he may be enabled to obtain a firm grasp of the great truths respecting animal and vegetable life, without which, notwithstanding all the progress of scientific medicine, he will still find himself an empiric?

CONCLUDING MEETING.

A vote of thanks having been accorded Professor Huxley, the concluding meeting of the Congress was held. The honorary Secretary-general (Mr. MacCormac) brought forward the following resolutions for the Physiological Section, which were submitted by the president and carried: "That this Congress records its conclusion that experiments on living animals have proved of the utmost service to medicine in the past, and are indispensable to its future progress; that, accordingly, whilst strongly deprecating the infliction of unnecessary pain, it is of opinion that alike in the interests of man and all animals, it is not desirable to restrict competent persons in the performance of such experiments." (Cheers.) The second resolution was from the Ophthalmology Section, and it contained a series of tests most applicable to persons employed in observing signals by land and by sea, where the lives of others were involved. These resolutions asked that the suggestions should be forwarded to the President

of the Board of Trade, first Lord of the Admiralty, and Secretary of State for Foreign Affairs, with the expression of the desire that they might be favorably entertained, and, if thought well, be recommended for adoption by foreign ports. As stated, the proposition was unanimously affirmed.

Commemorative medals were presented to Professor Donders and Dr. Guye, president and secretary-general of last Congress, and to Madame Raynaud, as a souvenir of her late husband. Commemorative medals were also presented to Professor Virchow, Berlin, Dr. Férrol, Paris, Dr. Billings, Washington, Professor Volkmann, Halle, Professor Pasteur, Paris, and Professor Huxley.

The fixture of the next place of meeting was left to the executive committee. On the motion of Dr. Billings a hearty vote of thanks was accorded Mr. McCormac, and the president (Sir James Paget), having delivered his farewell address, the proceedings were brought to a close.

In the evening the members of Congress dined together informally at the Crystal Palace, and thus was brought to an end the greatest international meeting of medical men that has ever been held.

The brief speech in which Dr. Billings proposed the best of all thanks to the honorary secretary-general was of the happiest possible character. The speaker stated that he had been asked in the morning his estimate of the amount of permanent good which would result from the Congress. He felt bound to liken the week that he and other members of the Congress had just passed through to an express railway journey through a richly cultivated land teaming with spots of interest, which, despite their undeniable individual importance or magnificence, could not help becoming a little blended together so as to leave for the moment but a confused visual and mental impression upon the semi-perplexed observer, who was not capable of at once recognizing the particulars of the very numerous impressions which he could not have failed to receive. Dr. Billings likening his own mental condition to the photographer's sensitive plate, declared that time and thought would effect a change, as by a developing solution, with the result that most valuable additions would have been made permanently to each individual store of available knowledge.

Professor Von Langenbeck, seconded by Mr. Prescott Hewitt, suitably proposed a cordial vote of thanks to those non-members of the Congress who had materially contributed to the great success and enjoyment of its session.

Dr. Guye, of Amsterdam, seconded by Sir Risdon Bennett, late president of the London College of Physicians, proposed hearty thanks to the officers of the Congress.

Mr. Bowman, the Nestor of ophthalmologists in this country, seconded by Professor Lister, announced the names of those before mentioned to whom medals of honor commemorative of the Congress were presented. Both proposer and seconder very briefly and as appropriately alluding to the most prominent causes of distinction attaching to each recipient of the souvenir, the audience, which even on this occasion in great part filled the principal galleries as well as the arena of the hall, showed by their always hearty but nevertheless modulated applause the proportion of high appreciation attaching to each one.

When the occasion arose for the president of this

Congress to finally address his admiring and distinguished audience, he must have indeed astonished most of them by the announcement that in the single week of the session the Congress had devoted more hours to the labor in its sections than were occupied during a whole year in the work of the whole thirteen medical societies of London, while the numbers attending each section far outstripped the average of those present at the most popular of the London medical societies; further, that the quality and the number of papers contributed during the week was unexampled, while very many of them came from authors who, independent of the Congress, would alone command a vast audience whenever they vouchsafed to lend themselves to afford intellectual entertainment to their hearers.

The change to Ryde to-morrow will indeed be an agreeable relaxation and delightful recreation for the many members of the Congress who will go to the annual meeting of the British Medical Association, of which Professor Humphrey is the president and Mr. Benjamin Barrow the president-elect. The address in medicine will be by Dr. Bristowe, while Mr. Jonathan Hutchinson will contribute that in surgery.

After the unprecedented sectional labors of the Congress, it has been wisely arranged that there shall be but four sections, medicine, surgery, obstetric medicine, and public medicine, as without doubt special sections would have been labor thrown away, as a most meagre attendance would have been unavoidable under circumstances which do not offer attraction to the mass of the general practitioners of the healing art.

LONDON LETTER: FROM A SPECIAL CORRESPONDENT.

LONDON, August 10, 1881.

MR. EDITOR.—The International Medical Congress for 1881 has just closed, and in compliance with your kind invitation I will notice some of the more salient points connected therewith, principally from a surgical point of view.

The smoke of the battle has not yet cleared away, and events have transpired in such rapid succession that details are for the moment very much confused. To borrow the simile that Dr. Billings used yesterday, it is like riding through the beautiful green fields and picturesque villages of England on an express train. The houses, fences, and other objects are passed so swiftly as to leave a blurred image on the brain. But time will bring out the details in our memory as the developing solution of the photographer makes the picture plain.

But certain things even now stand out in full relief.

There is no question that in the number and character of its delegates, and in the quality and amount of scientific work done, this Congress will always stand distinctly individualized as compared with any preceding one; and for many reasons, especially those of time and location, it will probably be a long time before it is equaled.

The register shows over three thousand names, but this is no guide to the number of actual attendants.

Very many registered, some by proxy, and never went near the meetings, but went sight-seeing and traveling over the country instead. Many others merely "looked in."

But the *real, working* attendance was very large.

Of course Great Britain contributed the great majority; next in numbers came the Germans; then the French; then Scandinavia, Russia, Italy, and Spain, counting these four as one — and next America. I am a little surprised that the United States was not more *largely* represented — I mean in all the departments. Only about a dozen men of national reputation in *general surgery* were among the active delegates. But with Bigelow of Boston, Little, Otis, and Sands of New York, Gross of Philadelphia, Weiss of Richmond, Gunn of Chicago, and Hodgen of St. Louis, you may be sure that American surgery was *properly* represented.

Tuesday afternoon was the time of the general reception at the College of Physicians. There the men from all parts of the globe who had only known one another through correspondence or by their contributions to the general fund of professional knowledge, met for the first time *vis-à-vis*. And a most interesting time it was — to shake hands with men whom you you have admired and revered for a life-time, and for the first time *talk* with them, and so many of them, is a rare experience.

I must not stop to tell you of the opening meeting. St. James's Hall was well filled. Everything was well done, but of course the report of committees was tedious. But the President's (Sir James Paget) address was worthy of his grand, noble self. At its close, as he said in the most impressive manner, "God help us in our work," I saw many eyes wet with tears, and I believe that every sincere worker in this Congress had his zeal and devotion quickened and warmed by the stirring appeals of our President to make the most of this rare opportunity.

Of course the real work was done in the sections. And here let me say a very pleasant thing. Although I spent most of my time in the Surgical section, yet once at least every day I dropped in to those of Medicine, Ophthalmology, and Gynecology, and often into others; and during the entire session I never saw nor heard of a single instance of anything but the kindest feeling and the most gentlemanly deportment.

The three topics of greatest interest in the Surgical section were Abdominal Surgery, "Intra Peritoneal," the programme had it, Modern Lithotripsy, — they wont say "Litholopaxy" over here, — and the Treatment of Wounds to secure Union by First Intention.

I may say parenthetically that the mode of procedure was for some one, or more, who had previously promised it, to read a paper upon the subject, and the discussion of those papers was taken up by the gentlemen appointed for that duty, whose names were printed upon the programme, and who were called in regular order by the president. And I may also say, right here, that every delegate was anxious to ascertain the exact position of "Listerism" in the convention. It was noticeable that early in the sessions when certain men, who shall be nameless, *seemed* to try to test the matter by initiating applause at every allusion to antiseptic surgery there was very little response. Mr. Lister himself was always and everywhere heartily received. But it required no great sagacity to see that the large majority of surgeons were *reserved* in the matter. But more of this further on.

Spencer Wells read a paper. He took strong Listerian ground, and said that now he had given up drainage altogether, so great was his faith in antiseptic

surgery. Several others, Volkmann especially, followed in a similar strain. Then Marion Sims arose, and while he declared for Listerism he advocated drainage, and reminded Mr. Wells of a case (ovariotomy), in which he assisted him in a bad operation, — had on account of adhesions, — and the patient *almost* died, but at last nature opened the abdominal wound and discharged a large amount of fetid fluid, and immediately she recovered. Finally came Mr. Keith to close the discussion. Never in the history of surgery did a few modest words make such a recoil in the "currents of expectant thought" as his.

It has been said, and was repeated by Volkmann and Kuget, in this discussion, that intra-peritoneal surgery was the "touchstone of Listerism." Professor Keith has been quoted the world over, again and again, as not only a warm disciple of Lister, but as illustrating in his remarkable success in ovariectomy, *more than any other surgeon*, the value of the antiseptic, or rather, the Listerian method. No one can deny this.

So slowly were his few words uttered that I can almost repeat every one *verbatim*.

You can imagine the effect much better than I can describe it when he said that for several months past he had "abandoned the antiseptic treatment altogether." "True," he said, "I had eighty successive recoveries under Lister's method, and *stopping there* it would be a wonderful showing. *But out of the next twenty-five I lost seven.* One died of acute septicaemia, in spite of the most thorough antiseptic precautions; three of "unquestionable carbolic acid poisoning; one of renal hæmorrhage." He went on to say that out of the eighty consecutive cases (or rather he said it first) many came too near dying; that a large number got a high temperature — 105°, 106°, 107° Fahrenheit — the evening following the operation, but, he said, "they happened to pull through." He then said that since he had for four months past abandoned the antiseptic method, and relied upon perfect cleanliness, care in controlling hæmorrhage, and thorough drainage, his cases were giving him much less trouble, and he was getting more satisfactory results.

He now stopped for a few moments, hesitating, as he must have realized the importance of his words, knowing that the whole world — surgical — was lending a "listening ear" to his utterances. The silence was "audible." Then he raised his head, and looking his audience squarely in the face, he said, "Gentlemen, I have felt it my duty to make these statements, for *they are true*," and took his seat. I shall not attempt to describe the applause, nor the effect of his statements. Professor Keith, by the way, told me privately that he almost died himself from using the carbolic acid so much. He got renal hæmorrhage and debility to an alarming degree. He said, moreover, that he never had great faith in it, and should not have continued its use so long — I mean the "Lister method" — but for the fact that so many eminent men were carried away with it; and if, after his remarkable series of cases, he had changed, and lost seven out of twenty-five, as he did, without Listerism, all the world — he himself — would have attributed the result to the change.

One thing is certain: Mr. Keith's statements, in connection with those of others and *his own experience*, put Mr. Lister in a very unpleasant position; for he was put down on the programme to close the discussion on the treatment of wounds to secure union

by first intention, which took place on Monday, 8th inst. Although four days had elapsed, he had no answer. To show how deeply he was impressed by all that had been said, he began his remarks, which were extemporaneous instead of written, as was expected, by saying that he never had admitted that abdominal surgery was the "touchstone of Listerism," and to the surprise and dismay of his followers went on to argue that, with the rapidity with which wounds of the peritoneum heal and the remarkable absorbing power of that membrane, and therefore its ability to take care of its exudates, he "doubted very much" whether, in the hands of a skillful, careful operator, it was not better to dispense with the antiseptic plan. I realize how important are the statements I am making, and lest some of your readers may think that they are open to criticism as to accuracy, I will say that I sat near enough to hear every syllable uttered, and I pledge my honor as a man and surgeon for the absolute accuracy of every statement, though I took few notes.

Then, seeming to realize the danger of admitting such wonderful absorbent qualities to the peritoneum, he went on to say that he had recently made some experiments that surprised him very much, which proved that serum or bloody serum was "a very poor soil for the development of germs from contact with air-dust, and that blood clots were still more sterile. Indeed, it was very difficult to make them grow or develop at all, unless diluted with water." By the way, he declared that he had witnessed free cell development in a blood clot.

And these remarkable facts, said he, "at once call in question the necessity of the spray."

He then went on to say that he was not yet ready to give up the spray, but if simple irrigation or lavation should prove as good, he would say, "*Fort mit dem spray*;" and he further said, "I am not certain but I shall give it up. I am not at all sure but that before the next meeting, two years hence, I shall have abandoned the spray altogether." (His recent house surgeon says that he has lost all confidence in its utility.)

As to carbolic acid, he said, "I am forced to admit its unfortunate character." That was all; not a word about oil of eucalyptus or any other substitute. He kept referring again and again to abdominal surgery, but his manner showed to everybody that he was upset.

He gave no statistics, no large comparisons, as was expected by his disciples. He referred to the excellent results in two cases of recent operation, saying that "I could hardly believe I should have got such results without the antiseptic plan; I did not before I used it."

And this is the fault that the best surgeons here find with him. They are all ready and glad to give him or any other man credit for all he has really done, and they all admit that Mr. Lister has done much to improve surgery, especially German surgery. I need not explain. But they very properly say, "With his unprecedented opportunities, both in his own practice and in that of his host of followers, why don't he give us large and complete statistics? Instead, he only gives either isolated cases or a small group of successful ones, such as may be found under almost any plan." I quote one of London's most eminent and fair minded men.

It was curious to watch the effect of the thing. I have alluded to the impression produced by Keith's remarks. As Lister was speaking, one of his ardent adherents — I mean an adherent of his mode of dressing; I am not discussing the man, who is an earnest hard-

working, accomplished gentleman — turned to me, and said, "My God, I would never have believed Professor Lister would have admitted that." Another said, "Well, if Lister abandons the spray and carbolic acid giving us no substitute, where is 'Listerism'? We had drainage, we had animal ligatures, we had air-proof dressings, before." And so on. Every little group of surgeons was discussing the matter; those who had never accepted the Listerian method being quite as much surprised as its warmest adherents.

"Mein Gott!" said a German whom I did not know, "Listerism ist todt." "Fort dem Spray? Fort dem Acid Carbolique? Was giebt's zu bleiben?" And so the pendulum swings.

The papers on Lithotrity, by Sir Henry Thompson and Professor Bigelow (I name them in the order in which they came), attracted much attention.

Sir Henry's was a clear, logical paper of trenchant quality, and he gave Dr. Bigelow credit for having demonstrated the heretofore unknown or unsuspected tolerance by the bladder of instrumentation. He was not inclined to accept his modifications of instruments for crushing or evacuating, and he protested very emphatically against the use of the larger-sized tubes. He claimed that they were unnecessary and dangerous, and that the smallest possible instruments should be used, both for crushing and evacuation, compatible with the prompt and complete removal of the stone.

Professor Bigelow's views are too well known to your readers to need repetition. Although he had a large display of instruments, lithotrites, and his evacuating apparatus in its various stages of "evolution," yet he admitted and insisted that the main point in his instruments was the large catheter or tube. He gave a beautiful demonstration of evacuation with his model, having a glass bladder filled with water, and using pulverized hard coal to represent the crushed calculus.

The venerable Mr. Clover claimed that his simple bulb and smaller tubes were all-sufficient, and that the projection of his tube into the bulb a little way, prevented the possibility of any return of fragments into the bladder, to prevent which Professor Bigelow has recently added a "Trap valve," which was shown in his illustration.

Mr. Brown, Sir Henry Thompson's partner, read a short paper denouncing the use of large and complicated instruments, and so on.

Sir Henry Thompson had his collection of stones present most artistically mounted and arranged. *Eight hundred calculi*, all labeled with the date of operation. All well communitated but one, that of the Emperor, part of which, in fragments, lay on one side of the cup, while, separated by a thin slip of brass, on the other lay the balance, as large as a pullet's egg, which he did not live to have removed.

The general feeling was that the *spirit* of Sir Henry Thompson's paper was open to criticism, while Bigelow won many friends by his calm, fair, candid manner and method; and whatever may be the final outcome as to detail in lithotrity, every surgeon gives Bigelow hearty praise and full credit for demonstrating not only the safety but, as a rule, the propriety of "lithotrity at one sitting" or "litholapaxy," as you please, while there can be no doubt that at this meeting of the Surgical Section, so far as sympathy and conviction on the part of a majority of the members go, Bigelow was in the ascendant.

But I must stop this rambling talk. I should like

so much to tell you of many things. Of Virchow's argument for vivisection, which, in the adoption of a well-framed and properly guarded resolution was unanimously and enthusiastically indorsed yesterday in the last general meeting. I would like to tell you of Professor Pasteur's remarkable address upon protective vaccination of the lower animals. Fowls protected against *chicken cholera*! sheep against *anthrax* and *charbon*! But I am not going to anticipate. Your pleasure is to come in the deliberate reading of these things. Finally, yesterday afternoon, came Huxley's memorable address upon the Relation of Biological Science to Medicine. While all were delighted with it—that is a commonplace expression—every one whom I have heard speak of it was amazed at his profound knowledge of the history and developmental progress of medical science. Do you know that he insisted on using the term pathology in its broad sense as synonymous with medicine in this address? I wish every man, practitioner and student, could have burned into his brain the words he used in his plea for a "*thorough knowledge of anatomy and physiology in the broadest sense as the essential fitness for the study of medicine.*"

A great admirer of Descartes is he, although he does not hesitate to criticise him freely. Said he, after declaring that there was no dividing line between health and disease, between physiology and pathology, except that which separated the comfort and safety of the organism from its discomfort and danger, and after a clear statement of the cellular doctrine, with a most graceful allusion to Virchow, "The first man who gave expression to this modern view of physiology, and who was bold enough to enunciate the proposition that vital phenomena, like all the other phenomena of the physical world, are, in ultimate analysis, resolvable into matter and motion, was *René Descartes.*"

Some of his metaphors were exceedingly felicitous. The following will sound somewhat familiar, but I quote it to give point to the next and last one that I noted. And I quote both because of his wonderful hope for and confidence in the therapeutics of the future. Constantly applauded as he was, yet when, by logical deduction from his premises, he prophesied for the coming man who thoroughly understood a true pathology the power to combat every form of disease he was cheered to the echo. Said he:—

"The body resembles an army; each cell, a soldier; an organ, a brigade; the central nervous system headquarters, a field telegraph; the alimentary and circulating system, the commissariat, and in which losses are made good by recruits born in camp, and the life of the individual is a campaign, conducted successfully for a few years, but with certain defeat in the long run."

Again he says, "I think I see how in the future it will become possible for the pharmacologist to enable the physician to affect in any desired way any function. It will become possible to introduce into the economy a molecular mechanism, which, like a cunningly contrived torpedo, shall find its way to some particular group of living elements and cause an explosion among them, leaving the rest untouched." Pregnant prophecy that, to him who is imbued with the doctrines of molecular physics.

"But," says our president, Sir James Paget, after all the graceful compliments have been paid and, in the persons of Charcot and Donders, Paris and Berlin have most delicately and elegantly tendered, in the

name of the Congress, our appreciation of his unexceptionable services, "all things come to an end, and the time has come to say 'good-by,' not good-by from me to you, but from each one of us to all. May all good and happiness go and abide with you; especially that greatest of all good that comes from doing good." And so it ended.

Very truly yours,

WM. WARREN GREENE.

THE BRITISH MEDICAL JOURNAL ON THE PRESIDENT'S WOUND.

THE above journal seems to have arrived at a pretty correct estimate of the character of the President's wound as early as July 30th, as the following extract from an editorial of that date shows:—

"The inference from this description is that the bullet never entered the abdomen at all, but that it passed into and is still lodged among the muscles of the back in the lumbar region. The tenor of all the symptoms which have followed the injury seems also to confirm this view of the case. There seems not to be the slightest ground any longer for suspecting the liver to have been involved in the wound. If it be true that the projectile, after striking the rib, was deflected into a path among the spinal muscles, its lodgment among them may give rise to comparatively slight inconvenience. The wound may in time become healed over it, the bullet may become encysted, and, unless excited into causing irritation by undue movement, or casual injury of neighboring parts, may lie quietly dormant for years. Or, in the process of the suppurative action during the treatment of the wound, the bullet may advance towards the opening with the discharges, be brought into view, and in this way an early opportunity of removing it may be afforded. Considering the nearness of the intended assassin to the President at the time the wound was inflicted, the pistol-bullet, it must be presumed, struck the rib with considerable force; and under these circumstances, inflammatory mischief will probably have been set up in the bone, which may render the healing of the wound a more tedious process than seems to be anticipated. The repair of a rib that has had a gun-shot injury, especially if it have been deprived of its fibrous investment, and have happened to be severely contused by the shot, is always a slow matter. But these complications are relatively unimportant when compared with those which must have been anticipated had the original suppositions regarding the nature of the wound and the course of the projectile been proved to have been well founded."

— At the request of the professors, the gentlemen of the English Army Medical School at Netley were addressed by Dr. Yandell, Professor of Surgery in the University of Louisville, at the close of the last session. According to the *British Medical Journal* the speech had every quality the occasion demanded—it was eloquent, manly, and sincere; and coming as it did from one who had done good service on many fields of battle in his country's cause, every sentence of it struck home, appealing, as the professor did, to the best and most generous sympathies of his audience.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 6, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3635 (no reports from St. Louis or New Orleans); 2035 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1593, diarrhoeal diseases 1066, consumption 332, diphtheria and croup 152, lung diseases 126, typhoid fever 89, scarlet fever 68, small-pox 57, cerebro-spinal meningitis 41, malarial fevers 39, measles 32, whooping-cough 31, puerperal fever 10, erysipelas eight. From *scarlet fever*, New York 28, Philadelphia nine, Pittsburgh eight, Brooklyn and Chicago five, Buffalo four, Milwaukee and Charleston two, Baltimore, Cincinnati, District of Columbia, Worcester, and Westborough one. From *small-pox*, Chicago 25, New York 12, Philadelphia 11, Pittsburgh seven, Brooklyn two. From *cerebro-spinal meningitis*, Chicago 10, New York five, Cincinnati and Lynn three, Philadelphia, Buffalo, Milwaukee, Worcester, and Fall River two, Boston, Providence, New Haven, Lowell, Springfield, New Bedford, Holyoke, Chelsea, Chicopee, and Woburn one. From *malarial fevers*, New York 11, Brooklyn eight, Baltimore five, Chicago four, District of Columbia, Buffalo, and New Haven three, Philadelphia and Charleston one. From *measles*, New York and Chicago 10, Pittsburgh four, Brooklyn and Milwaukee two, Philadelphia, Cincinnati, Buffalo, and Lynn one. From *whooping-cough*, Chicago nine, New York six, Baltimore four, Pittsburgh and Providence three, Philadelphia, Boston, Buffalo, Springfield, Chelsea, and Pittsfield one. From *puerperal fever*, Buffalo and Lowell two, Brooklyn, Chicago, District of Columbia, Milwaukee, New Bedford, and Holyoke one. From *erysipelas*, Chicago two, New York, Brooklyn, Cincinnati, District of Columbia, New Haven, and Springfield one. Eight deaths from sunstroke occurred in Chicago and six in Cincinnati.

Eight cases of small-pox were reported in Brooklyn, 40 in Chicago, 41 in Pittsburgh, scarlet fever 14, diphtheria four, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,033,140 (population of the State 1,783,086), the total death-rate for the week was 29.16, against 23.12 and 22.56 for the previous two weeks.

For the week ending July 16th in 149 German cities and towns, with an estimated population of 7,739,972, the death-rate was 31. Deaths reported 4678; under five 2212; diarrhoeal diseases 458, pulmonary consumption 420, acute diseases of the respiratory organs 263, diphtheria and croup 101, scarlet fever 81, typhoid fever 52, whooping-cough 48, measles and röteln 46, puerperal fever 12, typhus fever (Elbing, Erfurt) two, small-pox (Essen) one. The death-rates ranged from 12.8 in Metz to 49.3 in Berlin; Königsberg 36.9; Breslau 44.3; Munich 32.3; Dresden 29; Leipzig 25.4; Hamburg 25.2; Hannover 19.5; Bremen 25.1; Cologne 28.4; Frankfurt 20.8; Strassburg 41.8.

For the week ending July 23d in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 23.8. Deaths reported 3465: diarrhoea 652, acute diseases of the respiratory organs 152, measles 108, whooping-cough 90, scarlet fever 85, small-pox (London 43) 44, fever 30, diphtheria 20. The death-rates ranged from 14.7 in Bradford to 29.1 in Nottingham; Bristol 17.1; Birmingham 18.4; Sheffield 19; Manchester 22; Liverpool 23.5; Leeds 25.9; London 26.5. In Edinburgh 15.7; Glasgow 22.9; Dublin 24.3.

In the 21 chief towns of Switzerland, for the week ending July 23d, population 479,934, there were 50 deaths from diarrhoeal diseases, acute diseases of the respiratory organs 17, typhoid fever 10, diphtheria and croup six, measles three, whooping-cough one. The death-rates were: Geneva 22; Zurich 22.3; Basel 23.4; Berne 36.3.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

Deaths reported 3464 (no reports from St. Louis or New Orleans); 1884 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1430, diarrhoeal diseases 980, consumption 342, lung diseases 164, diphtheria and croup 142, typhoid fever 82, small-pox 54, scarlet fever 53, whooping-cough 38, cerebro-spinal meningitis 24, measles 21, malarial fevers 15, erysipelas 10, puerperal fever six, typhus fever five. From *small-pox*, Chicago 23, Philadelphia and Pittsburgh 12, New York seven. From *scarlet fever*, New

York 24, Brooklyn 10, Chicago five, Philadelphia four, Pittsburgh three, Baltimore and Worcester two, Buffalo, Milwaukee, and New Bedford one. From *whooping-cough*, Brooklyn nine, New York eight, Chicago six, Philadelphia four, Boston, Baltimore, District of Columbia, and Providence two, Cincinnati, Pittsburgh, and Newton one. From *cerebro-spinal meningitis*, New York six, Chicago four, Philadelphia and Pittsburgh three, Buffalo two, Boston, Milwaukee, Fall River, Lynn, Springfield, and Taunton one. From *measles*, New York eight, Chicago five, Milwaukee four, Baltimore two, Cincinnati and Pittsburgh

one. From *malarial fevers*, Brooklyn, Chicago, and Baltimore three, Philadelphia two, Buffalo, New Haven, Charleston, and Holyoke one. From *erysipelas*, New York four, Brooklyn three, New Haven two, Cincinnati one. From *puerperal fever*, Boston three, Brooklyn, Chicago, and Nashville one. From *typhus fever*, New York five. Deaths from sunstroke: Cincinnati three, Lowell and Amherst one.

Ten cases of small-pox were reported in Brooklyn, 32 in

Chicago, and 24 in Pittsburgh; scarlet fever seven, diphtheria five, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,090,732 (population of the State 1,783,086), the total death-rate for the week was 27.58, against 29.16 and 23.12 for the previous two weeks.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 6, 1881, TO AUGUST 19, 1881.

STERNBERG, GEORGE M., major and surgeon. Relieved from duty in connection with the National Board of Health, to proceed from Baltimore, Md., to San Francisco, Cal., and report to commanding general, Department of California, for assignment to duty. S. O. 182, A. G. O., August 10, 1881.

CORSON, J. K., captain and assistant surgeon. The leave of absence granted him in S. O. 61, May 31, 1881, Department of Arizona, extended two months. S. O. 179, A. G. O., August 6, 1881.

HALL, J. D., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for three months' extension, to take effect on final adjournment of general court martial, of which he is judge advocate. S. O. 141, Department of Dakota, August 4, 1881.

SEMG, B. G., captain and assistant surgeon. Granted leave of absence for six months, with permission to leave the Department of the Platte. S. O. 182, C. S., A. G. O.

PERLEY, H. O., captain and assistant surgeon. Granted leave of absence for four months. S. O. 178, A. G. O., August 5, 1881.

GARDNER, E. F., first lieutenant and assistant surgeon. The operation of paragraph 3, S. O. 171, C. S., A. G. O., in his case, suspended one month. S. O. 177, A. G. O., August 4, 1881.

WHITE, C. B., major and surgeon. Died at Wilton, Conn., August 10, 1881.

HUNNARD, V. B., assistant surgeon. Promoted to the rank of major and surgeon in the medical department, to take effect from the 10th of August, 1881, vice White, deceased.

BUSHNELL, GEORGE E., assistant surgeon. Granted leave of absence for fourteen days. S. O. 145, headquarters, Department of Dakota, August 9, 1881.

BUSHNELL, GEORGE E., assistant surgeon. Relieved from duty at Fort Yates, D. T., and to report to commanding officer, Fort A. Lincoln, D. T., for temporary duty, on expiration of leave of absence. S. O. 146, headquarters, Department of Dakota, August 11, 1881.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at Medical Library Rooms, 19 Boylston

Place, on the first Thursday of September, at 10.30 A. M. Paper by Dr. Field: Reports of Gynæcological Cases. Profession cordially invited. HENRY M. FIELD, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Rheumatism: Its Nature, its Pathology, and its Successful Treatment. By T. J. MacLagan, M. D. London: Pickering & Co. 1881.

On the Surgical Anatomy of the Sheaths of the Palmar Tendons. By Roswell Park, M. D. (Reprint.)

Coulson on the Diseases of the Bladder and Prostate Gland. Sixth Edition. Revised by Walter J. Coulson, F. R. C. S. New York: William Wood & Co. Wood's Library of Standard Medical Authors. Vol. VII.

First Annual Report of the Astronomer in charge of the Horological and Thermometric Bureau of the Winchester Observatory of Yale College, presented to the Board of Managers at their Meeting, June 3, 1881. By Leonard Waldo.

A Probable Cause of Tardy, Painful Labor not hitherto Recognized. By George H. Rohé, M. D. (Reprint.)

Transactions of the Maine Medical Association, 1853-1862. Transactions of the Maine Medical Association, 1880. Vol. VII. Part I.

Constitution, By-Laws, and Code of Medical Ethics of Maine Medical Association.

The Microscope and its Revelations. By William B. Carpenter, M. D. Sixth Edition, illustrated by twenty-six Plates and five hundred Wood Engravings. Philadelphia: Presley Blakiston. 1881.

A Guide to the Use of the Laryngoscope in General Practice. By Gordon Holmes, L. R. C. P. Edin. Philadelphia: Presley Blakiston. 1881.

The Functional and Morphological Relations of the Cerebellum. By E. C. Spitzka, M. D. (Reprint.)

Address delivered to the South Western Branch of the British Medical Association at Redruth, June 29, 1881. By William MacCormac, F. R. C. S.

A New Form of Nervous Disease, together with an Essay on Erythroxylon Coca. By W. S. Searle, M. D. New York: Forbes, Howard & Hurlburt. 1881.

On Eye Affections from Malarial Poisoning. By Charles J. Kipp, M. D. (Reprint.)

Lectures.

CLINICAL LECTURE ON SOME OF THE RESULTS OF CHRONIC INDURATION OF THE LUNG.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY A. JACOBI, M. D.,

Clinical Professor of Diseases of Children.

GENTLEMEN. — We have here a lad fourteen years of age, who comes to us to get relief for headache and bleeding from the nose, to which he is subject, and it must be our endeavor to find out, if possible, what the condition is upon which these symptoms depend. The history which he gives of himself is a very meagre one, and the only acute disease that he tells us of is an attack of inflammation of the lungs which he is said to have had when he was very young. You observe that he looks markedly anæmic, and that his general appearance is altogether that of one not in the enjoyment of good health.

When his chest is stripped you notice that there is more or less depression in the infra-clavicular spaces, and that there is a marked prominence of most of the external veins of the thorax. From the latter circumstance we naturally look for some obstruction in the lungs or heart, to which such a condition may be attributed. This enlargement of the veins indicates passive local congestion, and the headache of which he complains might well be dependent upon a similar condition about the head or brain. If there were, in conjunction with this, passive congestion of the pharynx a catarrh would result, and as the nasal mucous membrane is exceedingly well supplied with veins the nose-bleeding might easily ensue. Epistaxis is, therefore, very common in diseases of the heart and lungs.

But this state of passive congestion is not confined to the upper part of the body. The abdominal circulation is also impeded in consequence of such disease, which produces more or less disturbance there also, as we shall no doubt find in the present instance. In boys and girls epistaxis is not at all uncommon as a result of merely sitting for a considerable time with the body bent forward at school. This is attributable to the interference with the abdominal circulation caused by the position in which they are accustomed to sit; and hence in such cases, where there is frequently-recurring nose-bleed, it is often sufficient simply to take the children away from school and allow them to run freely about in the open air.

But, as I remarked before, in a case like this, where there is chronic enlargement of the superficial veins, we must look for the source of the trouble in some disease of the thoracic organs, and we will therefore institute a careful and thorough physical examination here. Beginning with the spleen, we find by percussion that it is considerably enlarged, measuring about four inches in length. This may possibly be the result of some former disease, such as intermittent or typhoid fever (although we have the history of no such attack), or it may be due to venous obstruction.

When we come to examine the liver we find that it is markedly enlarged, and that there is very considerable tenderness on pressure over the hepatic region.

On palpation the area of tenderness is somewhat circumscribed, occupying a sort of parallelogram about four inches in length and a little less in width, whose upper corner reaches to the bottom of the ensiform cartilage, and is bounded on either side by the lower border of the ribs. When percussion is resorted to, however, it is found that this area of tenderness becomes much greater in size, extending more than one inch lower (almost to the umbilicus), and also beyond the border of the ribs to the right, in the ordinary position of the right lobe of the liver. We should say, then, that there was some abnormal condition about the liver which affects the entire mass of the organ, which is greatly enlarged beyond its usual limits.

We notice also that the impulse of the heart can be perceived over an unusually large area, and on mapping out the heart by means of its percussion-dullness, we find at once that the organ is considerably enlarged. The dullness, however, does not extend very far to the left, though it reaches beyond the right edge of the sternum. When the ear is placed over the cardiac region we get a different murmur on both sides of the heart; but this I should conclude was due to the general anæmic condition of the lad rather than to any organic lesion. In young children it is very rare to find sufficient anæmia to produce such a murmur, or, rather, functional murmurs are rare in young children; but here, you must remember, the patient is no longer a child. We must look, therefore, for some other cause of the cardiac hypertrophy than an organic lesion. Sometimes this condition is due to over-exertion on the part of the heart in consequence of a long-continued obstruction of the lungs which has resulted in their partial imperviousness. On account of this the heart is obliged to do so much work in overcoming obstacles that it becomes permanently enlarged. Hence, in this case, if we should find present a pleuro-pneumonia of any extent, it would amply explain the condition of the heart.

On percussion we meet with a certain amount of dullness, both anteriorly and posteriorly, all the way down the chest on the right side; and on auscultation on this side we find also diminished respiration, both front and back, though somewhat coarser in the clavicular region than posteriorly. The signs point, then, to more or less solidification and induration of the lung, and it is altogether probable that there has been some thickening of the pleura also, though this does not appear to be the case at present. In this connection you will recall the fact that an attack of inflammation of the lungs was mentioned as having occurred in early life.

But, as has been indicated, the vena cava inferior, as well as the cava superior, is affected by this obstruction in the lung, and hence the trouble in the liver is explained. When the impediment to the circulation is very marked there is not only dilatation of the vessels, but effusion also results, so that the liver becomes permanently enlarged, as well as the heart. The liver would swell very much more easily, indeed, were it not for its comparatively unyielding peritoneal covering. As it is, the latter is put upon the stretch, thus giving rise to no little pain, because it will not expand to the same extent as the liver itself.

As to the condition of the spleen found in this case, this is due not so much to the trouble in the lungs or heart as to the abnormal state of the liver. You know

that in the third stage of cirrhosis of the liver, with contraction, enlargement of the spleen is exceedingly apt to occur, and the same result has here followed the engorgement of the organ produced by the thoracic obstruction.

What the boy comes to us for is simply to have his epistaxis relieved. If this is profuse it ought to be stopped at once, on account of the drain which is thus kept up upon his system. In such cases it is a very bad plan to wash out the nose freely with water and weak astringents, since this interferes with coagulation, which is essential for the control of the hæmorrhage. Styptic cotton (which is steeped in perchloride of iron), or the persulphate of iron would be a serviceable application. The closing up of the entire nasal tract by means of Belloc's canula is a safe procedure, and sometimes is necessary to effectually stop the bleeding. In connection with such measures we must not neglect to take care that there is no tight pressure about the body, and that the patient takes very deep inspirations, so as to fill the chest to the utmost extent, in order that there may be as small an amount of blood as possible for the nose.

The indications here are to do away, primarily, with the obstruction in the lungs, and, secondarily, with that in the heart and liver. The patient has had interstitial trouble in the lungs for twelve years, and though there is now no anphoric respiration, and not even bronchial breathing, it has been sufficient, as we have seen, to set up very considerable trouble in his system at large. If such pulmonary trouble were of syphilitic origin I would recommend mercurial inunction; but in this case there is no evidence whatever of this being the case, and such a course of treatment would not be of any service, especially as the boy is already very anæmic. On account of his anæmic condition iodine would also be contra-indicated, unless it were given in the form of the syrup of the iodide of iron. He certainly requires iron, and this is a preparation which is easily digested; but perhaps the most appropriate in such a case as this would be the pyrophosphate or dialyzed iron. The tincture of the chloride of iron would not answer, as it is a vascular stimulant.

Then the heart needs attention. When there is epistaxis depending upon mitral regurgitation it can often be stopped soon by the administration of iron and digitalis. A few small doses will often regulate the action of the heart in cases like this, and a lad of this age might safely take from five to six grains of it daily, or two minims of the fluid extract three times a day. On account of the stomach I would also give subnitrate of bismuth here.

Finally, as to the liver. The possibility of the presence of hepatic abscess may have occurred to some of you; but I find now that the temperature is only ninety-nine and a half degrees, while it would no doubt be considerably higher if such were the case. But though there is no abscess, there is, as we have seen, a decided irritation of the organ, producing great swelling and consequent stretching of the peritoneal covering. In normal digestion you know that the liver will swell more or less after every meal. With such a condition as is here present there is very apt to be some gastric catarrh, and therefore the bismuth will no doubt be of considerable service. Cold applications should be made over the region of the liver, and I would recommend that for the first day or two cold water should be used in this way continuously, and after that for a few hours

of each day. We have thus gone over a pretty large field in connection with this case, but I trust that you will feel that the time thus devoted to it has not been altogether misspent.

DESCRIPTION OF A DOUBLE MONSTER.¹

BY A. W. BLODGETT, M. D., BOSTON.

FÆTUS DICEPHALUS, HYDROCEPHALUS, ANENCEPHALUS, MICROCEPHALUS.

Mrs. R. E., a native of England, came to America while quite young; has always been in good general health. She is below the average height, is small in every way, but is very active. Married eight years ago, and in August, 1874, I was called to attend her in her first confinement. The labor was normal in all essential particulars excepting the fact that the head was slow to descend into the pelvis owing to a narrow condition of the upper antero-posterior diameter, it being reduced to about two and one half inches. After waiting a reasonable time forceps were carefully applied, under ether, and the head was easily brought down and delivery at once accomplished. The child, a small girl, was in a somewhat asphyxiated condition, but was revived and is still living. The mother was considerably prostrated, having suffered a considerable rupture of the perinaeum, and was for some days unable to micturate, but eventually made a good recovery. In November, 1875, I was again called to attend this patient during a miscarriage at the fourth month, brought on apparently by overwork. From this she made a rapid and complete recovery. November 25, 1875, I again attended this lady in confinement at full term. She had been very well during her pregnancy and took entire charge of all her household affairs until the night of her confinement. Pains had been severe for four hours, the os was slowly dilating, the occiput was toward the left acetabulum, the membranes not ruptured. After three hours the membranes were ruptured and the head descended somewhat, but became firmly fixed upon the brim of the narrow pelvis and did not subsequently move, although the pains were vigorous. Six hours later forceps were applied, under ether, and after about fifteen minutes' hard labor a living child was extracted. The child, a large boy, was deeply asphyxiated but was resuscitated and is still living. Considerable hæmorrhage took place upon the delivery of the placenta, but was controlled by means of brandy and ergot. The perinaeum was slightly lacerated and the child's head sustained considerable bruises, but these soon disappeared without any consequences. The mother made a somewhat slow recovery owing to the strain, and pressure in the pelvic region, but she escaped any serious disease, and in a few weeks was as well as before her confinement. January 3, 1881, I was again summoned to attend this patient in childbirth. This pregnancy had been more burdensome to her than any previous one, owing to an unusual protrusion of the abdomen forward over the pubes, a so-called "pendulous abdomen." The prominence was so great that the axis of the uterus inclined forward at about the angle of 45°. The discomfort of the patient was no doubt materially increased by the

¹ Read before the Obstetrical Society of Boston and published at their request.

apprehension of trouble at the time of delivery. Patient says she has felt the motions of the child principally in the left epigastric region. It is impossible to make out the position of the child by external palpation, owing to the high position of the head and the large amount of liquor amnii. The os was found dilated to about five cm. and the occiput to the right acetabulum. Fœtal pulse strong and regular. Labor pains were moderately intense, the mother's condition was good. From eleven p. m. to five a. m. January 4th, there was no change in the position of the head. At this time the mother began to show signs of exhaustion and ether was administered when the membranes ruptured and an enormous quantity of liquor amnii was evacuated, but there was no material change in the position of the head. At seven a. m. Dr. Reynolds was called in consultation, and coincided in the opinion that artificial assistance was necessary, as the condition of the child was becoming perilous. Long curved forceps were at once applied and took firm hold, but repeated powerful traction produced no effect upon the position of the head. Dr. Reynolds then suggested farther consultation, which could not be obtained. Version was then attempted, and after a time was successfully accomplished and the right foot brought down. The left was soon brought down also, and the trunk followed. The right arm was delivered and the body turned so as to release the left arm, which was delivered with some difficulty. There was a strange malformation in the neck and shoulders which somewhat hindered the delivery of the head, and which it required some traction to overcome. The head was born after a short interval, and with it came a gush of blood in which the placenta and membranes were expelled entire. The child was stillborn. Examination disclosed the astonishing fact that the child was a monster of a very rare and interesting character.

The lower end of the vertebral column was open, forming the condition known as *spina bifida*. A space about five by two cm. was devoid of all external bony inclosure, the only coverings of the vertebral canal at this point being the membranes of the cord. The skin terminated abruptly at the margins of the fissure by a well-defined edge. The vertebral column was divided into two at the level of the superior angles of the scapulae. One vertebral column extended upward in the line of the body and supported a well-developed head with all the features of the face perfect and well formed. The cranium was hydrocephalic to a marked degree, the bones of the skull being separated by the distension, so that the two lateral halves of the frontal bone were freely movable upon one another. There was considerable œdema of the scalp. The second vertebral column followed a direction to the left at an angle of about 30° and passed into a second neck which protruded from the body at a point between the proper neck and the left shoulder. Its circumference was about half that of the natural neck. It supported a second head which bore the proportion of about one half in all measurements in comparison with the natural head, except in those special relations which will be noticed further on. The mouth and tongue were perfectly formed, the eyes were present, the pupils and irides had a normal appearance, and all the details of facial structure were well carried out. From a line just above the eyes the head was perfectly flat from before backward to a point near the junction of the head and neck. Upon this portion of the head there

was only a soft membranous covering, and upon raising this at the border, where it was folded to join the external skin, the bones of the base of the skull were felt covered only by the membranes above alluded to. In the centre could be felt the foramen magnum of the occipital bone. There was no brain substance contained in the membranes, nor could the medulla oblongata be detected. The ears were situated in their natural position on both sides but were very near the border of the cranial bones. The lobes were turned or rolled inwards upon themselves and appeared as if deformed, but they could easily be unrolled, when they were seen to be normal in shape and only proportionally small in size. The nose was pervious, there was neither cleft palate nor hare lip, or any other indication of defective formation. The hands and fingers as well as the feet were perfectly normal. The external genitals were those of the female and consisted of well developed labia and a perfect hymen. Dr. W. F. Whitney made a careful study of the relations of the internal organs and has presented the following admirable report, which he has kindly given me permission to include in the account of the case.

Externally the monstrosity presented two separate heads and necks with but two arms, the spinal columns from neck to sacrum distinct but closely united side by side. This condition is known as *Dicephalus Dibrachius Dianchinus*. (Foerster.) One of the heads was hydrocephalic, the other anencephalic, and there was a common *spina bifida* of both spinal canals from the lower lumbar region. The length of the fœtus was fifty cm. and its weight 3530 grammes. One head (which with the viscera standing in direct relation to it will be called A) measured fifty cm. in circumference. The sutures were wide, the bones parchment-like in feeling, and the cranial cavity filled with watery serum in which was softened brain substance.

The second head (called B) measured sixteen cm. in circumference. The vault of the cranium was entirely wanting, and replaced by a dark reddish mass of softened tissue resting directly upon the base of the skull. The frontal bone was very narrow, and directed almost horizontally backwards, thus rendering the orbits very shallow, causing the eyes to protrude, and giving to the whole face a frog-like aspect. Upon dissection it was found that the muscles of the right side of the neck of A had their origin in the normal manner, while the muscles of the *left* side of A and of both sides of B had a common origin, and afterwards subdivided. There were but two omohyoids, passing to the right side of A and the left side of B respectively. With each head was an œsophagus distinct throughout its course, with which was connected a stomach with its fundus directed outwards. The duodenum from stomach A was very short, and opened into that of B about 3.5 cm. from its point of origin. From this point the intestinal tract was single and normal. The liver was large, with two gall-bladders and ducts, which opened separately into the duodenum of B just above the point of entrance of the duodenum of A. Lying above the diaphragm in the space between the vertebral columns behind and the pericardium in front, and in the same sac as the lungs and just below them, was a portion of liver three cm. long by two cm. broad, of a roughly oval shape. This was apparently connected with the large liver by vessels passing downward through the diaphragm. Whether this is to be considered as a distinct rudimentary

mentary liver or as merely a misplaced lobe I cannot state, but the existence of the two gall-bladders on the larger portion points rather to a doubling, with fusion, and in that case the latter hypothesis is more correct. Attached to each stomach in a relatively normal position was a pancreas. The spleen was single, and attached normally to the stomach of B. Each head had a separate larynx and trachea. Each trachea divided into two bronchi, each of which stood in communication with a lung. The two pairs of lungs lay one on each side of the two vertebral columns in

a common pleural cavity. The right lung of pair A and the left lung of pair B were smaller than their fellows. The hearts, partially doubled, lay in a common pericardial sac. The auricular portions were united into a common cavity divided by two partial septa into three compartments, one connecting directly with the ventricular portion of A, and the other two with the right and left ventricles of B. Into the compartment opening into the right ventricle of B there emptied the vena cava superior, which received the blood from the two heads and the upper extremities;

the vena cava inferior and the pulmonary veins from the lung of A; the pulmonary veins of B emptied into the compartment connected with the left ventricle of B. The ventricular portions of the two hearts were separate; the portion belonging to A presented but one cavity, subdivided by a septum reaching three quarters of the distance from the apex to the mitral valve (the tricuspid being wanting). From this ventricle passed off the aorta, and there was a small fibrous string (probably the remains of the main trunk of the pulmonary artery) connecting the ventricle with one of the pulmonary branches. The aorta arched in the usual way, and after giving off the two carotids, the subclavian for the right arm, and the ductus Botelli, it passed into the furrow between the two vertebral columns, where it was joined by its fellow, and was normal in its further distribution. In consequence of the obliteration of the pulmonary artery the lungs of A received their blood from the aorta through the ductus Botelli, it connecting with the branches passing to both lungs. The ventricular portion of B was normally divided, and from the two ventricles were given off the aorta and pulmonary artery. The arch of the aorta gave off a short, thick trunk from its summit, which soon divided into the two carotids. At the commencement of the descending portion the left subclavian was given off, and opposite to this the ductus Botelli received. The pulmonary artery presented no marked deviation, except that it was directly continued as the ductus Botelli, the right and left branches being small.

In summing up the changes found in the viscera they are seen to consist of a doubling of all the organs above the spleen, and of special note are the portion of liver above the diaphragm in the pleural cavity and the fusion of the ventricular portion of the heart A, with obliteration of the pulmonary artery, necessitating the blood passing to the lungs from the aorta through the ductus Botelli.

This monstrosity belongs to a class of beings described by Foerster in his work *Die Misbildungen des Menschen* in the following terms: Order, *Terata katadidyma*, being one of the group of monsters with downward cleavage. Genus: dicephalus, double headed. Species: dibrachius dipus, possessing but two arms and two feet. Variety: dianchenos, possessing two vertebral columns and two distinct necks.

The further designations of hydrocephalus and anencephalus relate to the accidental conditions of the cranial cavity in the two heads, both of which have been the seat of dropsical effusion, either into the ventricles of the brain or outside the cerebral substance in the subarachnoidal space. In one case the early embryonic cerebral matter has been entirely disintegrated and destroyed by the effusion, with subsequent rupture of the cranial envelopes and collapse of the membranes of the brain, so that complete anencephalus results. In the other head the same condition of dropsical effusion has existed, but to a less extensive degree. The pressure within the cranial coverings was not sufficient to rupture the membranes, the cranial coverings have been developed in a normal manner, the squamous bones are present, the tissues of the scalp are well developed, and the head though large is still intact, and many cases of hydrocephalus in the more moderate degree survive for months or years.

The lack of closure of the vertebral column, constituting the condition of spina bifida, is due also to the

presence of a large effusion within the spinal membranes, which prevents the proper closing of this canal. The membranous sac containing the fluid usually ruptures before birth, though by no means always, when the sac collapses into a mass of wrinkled membrane at the seat of the fissure. Cases of spina bifida generally succumb to inflammatory processes of the membranes of the cord or brain, or both. Cases sometimes survive to adult life, but generally are afflicted with some functional disability in parts supplied from the spinal cord.

Dicephalic monsters are among the most frequent varieties of double development. Foerster states that of five hundred cases of double monsters one hundred and forty were dicephalic, of which thirty-four were males and sixty females. There is a far greater frequency in deformities of all kinds in the female sex, and fully two thirds of this class of monsters are of the feminine gender. The dicephali are viable unless some accidental defect in the internal organs exists which interferes with the functions of the nervous, circulatory, or alimentary systems. Cases have been known to survive through a long life, and several are at present living, among which perhaps the one best known is the negro girl called the Two-headed Nightingale.

The duplication of the vertebral columns is complete to the sacrum, constituting the condition termed *dianchenos*. The medial ribs from each vertebral column are fused, and extend as short horizontal processes from one vertebral column to the other. Each medial rib has a head and articulating surface on each end, by which it is attached to the two vertebral columns in the normal manner. The lateral ribs are attached to the outer surface of each vertebral column in the usual manner, and pass around the chest to be united to a common sternum in front. Their appearance

is in no way peculiar, excepting that they are curved somewhat differently from the normal ribs, giving the chest a more cylindrical appearance than usual. Only two clavicles are present, corresponding to the two scapulae. The musculature of the two necks is in a general way normal in each, the variations being only those to accommodate the duplication of the parts.

The condition of the thoracic and abdominal organs is very interesting as showing the effort at unity of function in duality of organization. The lungs were double, but were fused in their medial portion. It is doubtful if the air channels of one side had any communication with those of the other. There was no apparent obstruction to respiration in either set of respiratory organs. The hearts were contained in the same pericardial sac, and were fused in such a way that the cavities were more or less common to both organs, but presented nothing which would have been an obstacle to a sufficient function to sustain life. The stomachs were each complete, and each opened by a pervious canal into a common duodenum. The livers were plainly fused, coming into contact at a point near each gall-bladder, so that the two gall-bladders and separate gall-ducts lay side by side and opened by similar orifices into the duodenum. A portion of the liver was misplaced, and lay above the diaphragm in the cavity of the thorax. It is not a very rare thing to observe the large viscera divided and located in abnormal positions, this being quite frequently noticed in the spleen, but I have not before seen any of the abdominal organs transposed into the thorax. The genital organs show no signs of duplication. They are those of the female, and are complete and normal.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.

BY F. I. KNIGHT, M. D.

TUBERCULOSIS IMPLICATING THE MOUTH AND THROAT.

MR. LENNOX BROWNE and Dr. Dundas Grant have a very interesting and beautifully illustrated paper on this subject. (*Archives of Laryngology*, vol. ii., No. 1.) They say, in the beginning, that, thanks to the recent researches of our fellow-workers, more especially those of Isambert, Wendt, and Heinze, so much advance has been made in the pathological study of tuberculosis as affecting the pharynx and larynx, that it may now be considered an accepted fact among laryngoscopists that tubercle, as such, does exist, and does pass through all its pathological phases in these regions—a point on which they venture to think the writings of Louis, Rokitansky, and Virchow should have sooner obtained a general consensus of opinion. There does not, however, seem to be the same amount of unanimity on certain points of clinical interest in connection with the subject; as, for example, whether the throat can be affected primarily, and whether tuberculous ulceration assumes such a type that it can with certainty be diagnosed by means of the laryngoscope during life, and independent of other commemorative signs and symptoms, in the firm assurance of confirmation on autopsy. Details of five cases, by no means specially selected, are given, and then follow opinions founded upon them and oft-repeated similar observations. In the first place they call attention to the fact that the cases have

not been described under the heading of laryngeal or pharyngeal phthisis, because it did not seem to them desirable, in the present state of our knowledge, to enforce the theory that there can be tuberculous disease in either of these regions, independent of a similar lesion in the lungs. At the same time, it cannot be stated for certain that such manifestations arising in any part are necessarily secondary to the occurrence of disease in the chest. Nor can either of these questions be definitely settled until an opportunity occurs of dissecting subjects of tuberculosis of the throat in whom there are no evidences of disease in the chest. The clinical evidence at present in our possession, in favor of a possible primary occurrence of tubercle in the throat, is of a two-fold character, commemorative and objective. Of the former kind is the not unfrequent account given by patients of the loss of voice, laryngeal pain, and difficulty of deglutition prior to the appearance of any symptom of pulmonary disease. The objective evidence is well illustrated in several of the cases reported, but especially in one, in which the disease was diagnosed in the larynx when the lungs were still healthy, or, at all events, at a time when the eye could distinguish the visible changes in the larynx long before the changes, if any, in the lungs, were appreciable to the faculty of hearing.

The causes of the disease are fairly illustrated in these cases. We find, as an invariable element, a low state of vitality either inherited or acquired. Less invariably is there some local irritation, in which the continued strain on the patient's vocal organs in the pursuit of his calling (as in the case of the auctioneer) produced what in an individual of greater power would, with proper care, have passed off as a simple laryngitis. In another instance the local irritation of diseased teeth, as proved by the improvement following extractions, was the exciting cause of tuberculous ulceration of the gums and mouth. In several there was temporary improvement in summer or on favorable change of residence. The symptoms in the cases narrated are so typical as to enable even those unaccustomed to the use of the laryngoscope to diagnose the condition with tolerable certainty. Briefly, the emaciation and loss of weight, night-sweats, aphonia, cough with profuse laryngorrhoea of semi-purulent character, pain only in deglutition, more marked in the case of fluid, with tenderness on pressure of the larynx, afford an unmistakable picture of the disease in question. In cancer, besides its more marked cachexia, the disease is distinguished by the constant presence of pain, independent of functional acts, as well as its occurrence during deglutition, being more intense in the case of solid than of fluid. Syphilis gives a hoarse rather than an aphonic character to the voice, is on the whole free from pain, and has other symptoms of its own sufficiently distinctive to afford a reliable guide. It is, however, only by a recognition of the characteristic appearances as reflected in the laryngoscope, that a certain diagnosis can be made. These appearances are the peculiar semi-solid swelling and worm-eaten ulceration of the epiglottis and aryepiglottic folds. The swelling is often much greater on one side than on the other, but we never see tumefaction of the tissues covering one arytenoid cartilage much advanced without a similar condition existing to some extent over the other side also, thus distinguishing it from cancer, and from non-tuberculous perichondritis. The authors do not agree with Ziemssen, Mackenzie, Cohen and others

that there is nothing definitely characteristic in the appearance of the tuberculous ulcer. They say that with the exception of laryngeal growths, they know no disease in which, with the laryngoscope, we can be so sure of our diagnosis. They hold that, given the characteristic gray semi-solid infiltration of epiglottis, aryepiglottic folds or both, — an appearance almost invariably the precursor of ulceration, — there is a form of ulcer superimposed on the swollen tissue, which they believe distinctly characteristic, and which we are able to foretell is incurable. In the absence, however, of the thickening, the character of the ulceration is hardly less typical. The points to which they call especial attention are these: The floor of a tuberculous ulcer is pale and granular and slightly depressed, the margins are fairly well-marked but not deeply excavated, the surrounding parts pale and "languid," and there is an appearance of a spreading process of erosion very comparable to that of the nibbling of a small rodent animal. This is due to the confluence of small ulcers produced by the slow incurable inflammation of the mucous and closed follicles of the mucous membrane, and also to the ejection of minute tubercles which have worked their way to the surface. Very different from this is the punched-out areolated excavation which is seen in tertiary syphilis, and which may be considered suggestive of a bite rather than of continued nibbling. The prognosis of the disease is considered unfavorable both as regards recovery and duration of life.

In regard to treatment, the authors have found iodide of potassium and local scarification recommended so highly by Schmidt, of Frankfort, injurious rather than beneficial. Their experience leads them to subscribe cordially to the opinion expressed by Krishaler, Ziemssen, and others, that although a tuberculous ulceration in the throat may heal, as in other parts, such a process is certain to be followed, sooner or later, by an outbreak in close proximity. The disease may even become chronic and lie dormant, but not even the most sanguine throat specialist is yet justified in giving even a moderately hopeful opinion as to result.

The treatment recommended is cod-liver oil, especially combined with maltine and the hypophosphites. Locally, a well-thickened mixture containing small doses of morphia is most efficacious, when slowly sipped, in allaying pain and cough. The most generally useful application to be made with the brush is one of chloride of zinc, morphia, glycerine, and water. This is considered a better mode of application of morphia than the usual insufflation with powdered starch, etc. One patient was apparently much relieved in deglutition by the frequent application of a mixture of the compound tincture of benzoin, compound tincture of camphor, tincture of belladonna, and yolk of egg. Galvano-cautery, while it gave no relief in a case of tubercular ulcer of the tongue, certainly proved beneficial in a case of faucial tubercle. Scarifications seemed urgently called for in one case, and possibly relieved immediate risk of complete obstruction to the larynx, but certainly the rapid spread of ulceration at the punctured spots proved the inadmissibility of this plan of treatment. In regard to rest of the larynx by adopting the rectal mode of feeding and tracheotomy, the authors say that the insufficiency of nutrient enemata for the support of an individual whose assimilative power is at a minimum seems too obvious to require much experimental proof, but in case where the diag-

nosis was doubtful it would be only right to give this plan of treatment a fair trial. As regards tracheotomy it is only necessary to bear in mind the essentially unstable condition of the lungs in a subject of laryngeal phthisis, to restrain us from admitting cold air through any shorter warming passage than that supplied by nature. Again, from a pathological point of view, the rapid degeneration of cartilage met with in this disease would offer little inducement to the infliction of a wound on the windpipe with the subsequent retention of an irritating foreign body in the shape of a tracheal canula. Soft, thick food is generally the most acceptable, such as raw eggs, whole or beaten up. Oysters, thickened soups, and milk will suggest themselves as suitable in less extreme cases.

SURGICAL TREATMENT OF HYPERTROPHIC NASAL CATARRH.

Dr. Wm. C. Jarvis, of New York, gives an account¹ of his method of removing hypertrophied mucous membrane from the posterior ends of the turbinated bones. As is well known, the swelling of the posterior ends, particularly of the inferior turbinated bones, causes oftentimes complete obstruction to nasal respiration, and the greatest annoyance to the patient. A radical cure can be effected only by the removal of the hypertrophied tissue. Dr. Jarvis's instrument bids fair to be a permanent addition to the armamentarium of all who treat these affections properly. It is a wire snare *écraseur*. It consists of two metal canulae, the large one is six inches in length, and flexible, the smaller about four inches long, slides freely upon that part of the main one nearest the operator. The surface of the main canula occupied by the secondary one is threaded for the movement on its surface of a milled nut. Wire is passed through the main canula and attached to two retention pins fixed to the proximal ends of the small one. A slight indentation upon the small canula fits a corresponding surface on the large one. This arrangement prevents rotation of the secondary canula, and so overcomes the tendency of the wire to twist and become loosened from its attachment to the growth. The nut, when turned, pushes the outer canula before it, its speed ranging from an imperceptible advance to a rapid motion along the thread. In using the *écraseur*, pass the two ends of the wire through the main canula, entering them at its distal extremity, and twist them around the retention pins. A loop is formed, whose size, of course, depends upon that of the growth. Giving the wire loop a twist toward the side of the nose occupied by the growth, it is fixed by a turn of the nut, and passed into the nostril. Holding the rhinoscopic mirror in one hand, the position of the wire loop in the posterior nares is carefully watched, while it is steadily advanced with the other hand until seen to encircle the growth. On drawing the wire home the tissue is cleanly divided, and if not too large to pass through the nares it will generally be drawn out clinging to the snare. Make traction very slowly, stopping at short intervals in order to cause the slightest amount of hæmorrhage. The hæmorrhage is trifling provided slow traction is made. It consists usually of one or two small clots blown out upon the handkerchief. [Our experience with the instrument has been that considerable though not alarming hæmorrhage may follow the operation, even when very slowly performed, profuse hæmor-

rhage if it is done at all quickly. An hour or more should be consumed in the operation, a few twists only being given at a time. *REP.*] For the wire No. 5 piano wire is usually employed. Sometimes, on account of the tendency to gag, it is necessary to tie up the soft palate. The wounded surfaces rapidly heal, and the good results of the operation soon manifest themselves. The immediate result of the operation is a restoration of free nasal respiration. As the nature of turbinated hypertrophies renders their return almost impossible, the establishment of free nasal breathing is apt to be permanent. This is made more certain by the cicatricial contraction which follows. Since the most intense inflammatory processes are centred in the tumefied tissues their removal does away with the active source of the disease. The remarkable cessation of the catarrhal secretion, which often follows the removal of these growths, points to the cause and seat of this disease. Pressure exerted by the hypertrophied turbinated tissue is of itself an active agent toward the excitation of undue nasal secretion. Relief of the pressure naturally relieves the discharge.

(To be concluded.)

INTERNATIONAL MEDICAL CONGRESS, 1881.

AN ADDRESS ON THE VALUE OF PATHOLOGICAL EXPERIMENTS.²

BY RUDOLF VIRCHOW, M. D.,

Professor in the University of Berlin.

As reporter on Medical Education at the last International Medical Congress, held in Amsterdam, I raised the question, how far the experimental method is necessary to instruction; and the result at which I arrived was, that the use of this method to its greatest extent, and especially of vivisection, is an indispensable means.³ In a still higher measure, however, I had to raise into prominence the importance of this method in research; and, in opposition to those who, with constantly increasing vehemence, brought accusations against the experimental investigators on account of the direction and method of their researches, I was able to say, with the lively assent of the numerous members of the Congress, and without one word in contradiction: "All those who attack vivisection as a means of science, have not the least idea of the importance of the science, and much less of the importance of this aid to knowledge."

In the two years which have since passed away, the agitation of the opponents has grown both extensive and important in its object. One country after another has been drawn into their net, and international combinations have been formed, in order by united force to obtain greater results. No increase of satisfaction has been produced by the concessions made in 1876 by the legislation in England. The demands have increased: a petition from the new Leipzig Society for the Protection of Animals, dated March 8th of the present year, desired of the German Reichstag the enactment of a law by which "cruelty to animals under the pretext of scientific research" should be punished "with imprisonment for periods of not less than five

² Slightly condensed from the British Medical Journal.

¹ Transactions of the American Laryngological Association, 1880.

weeks to two years, and with simultaneous deprivation of civil rights." All, indeed, do not go so far. Many do not demand that all experiments on living animals should be at once suppressed, but that there should be limitations, some demanding more, others less. But even these do not make it secret that this concession is only provisional; and they demand that even the official laboratories of the universities should be placed under the control of the members of the Society for the Protection of Animals, so that the members may be at liberty to enter the laboratories at any time.

It would be a mischievous delusion to believe that this movement is without prospect of success, and devoid of danger because of its manifest exaggeration. On the contrary, unmistakable signs indicate that it has gained powerful allies, and that there is an increasingly impending danger in many countries that even the state institutions, created expressly for the purpose of experiment, may have the scientific freedom of their methods attacked. So much the more does it seem to be incumbent on the representatives of medical science to defend their position, and to meet international attacks by international weapons. *The most powerful weapon, however, is truth*; and here, above all, *truth founded on competent knowledge*. If we cannot demonstrate our good right before all the world, and come to a mutual agreement on the ground of this right, our cause must henceforth be looked on as a lost one.

The attacks which are directed against us fall, when closely examined, into two categories, according to the principal point. On the one side, it is alleged that the experimental method — yea, modern medicine altogether — is materialistic, if not nihilistic, in its ultimate object; that it offends against sentiment, against morals. On the other side, it is denied that the introduction of experiments on animals has had any actual use, that medicine has been really promoted thereby, and especially that the cure of diseases has in consequence made any recognizable progress. Even those who admit that there has been some progress, yet believe that just as much information could have been imparted by anatomy alone as by experiments on living animals.

Such objections are not new to one who knows the history of medicine. For hundreds of years, on similar or identical grounds, the dissection of human bodies was impeded, and anatomists were confined to the dissection of dead animals; if, indeed — as was done by Paracelsus, the contemporary of Vesalius — the insulting question were not asked, whether anatomy was of any use at all. The feeling of the masses was raised against the dissection of human bodies; and it is known that, at the commencement of the fourteenth century, the church for the first time gave permission for this to be done, but only under limitations which were still greater than those under which the larger number of our modern opponents would permit vivisection. It was no accident that the period of the reformation in the church first created for the great Vesalius a free field, so that he might test the truth of Galen's traditional dogmata by his own investigation of human bodies, and place true human anatomy in the stead of the anatomy of animals, which had during centuries formed the groundwork of all medical ideas on the internal arrangement of man.

And now, first of all, pathological anatomy — what obstacles it has had to overcome even in the present time! Nothing is more instructive in this respect than the narrative which Wepfer, the celebrated discoverer

of the hæmorrhagic nature of ordinary apoplexy, gives of the acts of enmity with which he was persecuted when — it was towards the middle of the seventeenth century — the council of the town of Schaffhausen had allowed him to dissect the bodies of those dying in the hospital. The only reply which he made to those who said to him that it is injurious and disgraceful to soil his hands with blood and sanies, was, that he could cleanse his hands with some water; but that much more disgraceful and injurious is ignorance of anatomical facts, which inflicts on inexperienced physicians and surgeons a disgrace that not the Rhine, not the ocean itself, can wash away.¹ Hence the study of anatomy is much rather to be praised, and to be supported by those who exercise the executive power in the State.

In fact, one government after another has recognized the decided importance of anatomical science. As far as the civilized world extends, so far at the present day are human bodies dissected. Even the laity comprehends that, without the most accurate knowledge of the structure of the human body and of the changes which disease and recovery produce in it, skilled action on the part of the physician is impossible. Any one who can only take a general survey of the history of science, must know that both the greatest epochs of the resuscitation and reformation of medicine commenced with the definite establishment of both the principal branches of human anatomy, and were even essentially brought about thereby. In the sixteenth century, it was physiological anatomy which brought about the definitive victory of empiricism over dogmatism, of science over tradition; in the eighteenth century, it was pathological anatomy which replaced mysticism by realism, speculation by necropsy, obscure groping and guessing by systematic thought.

No one can be more disposed to concede the high value of anatomical studies to the development of medicine, than one who has made it a part of the task of his life to place anatomy and histology in that commanding position in the recognition of his contemporaries which they deserve. Nothing lies further from me than to discourage those who still expect the greatest benefit to the practice of medicine to arise from following out these studies. May indeed the growing youth, who will have to follow us in assuring the progress of medicine, learn from our example how useful it is to lay the true foundation of our science in anatomy. Assuredly, much of that which remains dark to us will then be rendered clear.

But we must not allow ourselves to be forced back on this way as the only permissible one. Were the attempt to hinder totally or in great part researches on living animals to become successful, the same procedure which has been now entered on against vivisection, would also be commenced against mortisection. There would no longer be societies for the protection of animals, which we see opposed to us, but societies for the protection of human bodies. There would no longer be thunderings against the tormenting of animals, but against the desecration of corpses. Under the standard of humanity, which is just now unfurled even for animals, there would be preached in a still more impressive manner the campaign against the barbarity of med-

¹ Joh. Jac. Wepfer. *Observ. Anat. ex Cadaveribus eorum quos sustulit Apoplexia*. Schaffhusen, 1658. *Præcipio: Turpius et damnosior rerum anatomicarum ignorantia est, quæ imperitis Medicis et Chirurgis ignominiam parit, quam nec Rhænus, nec Oceanus ablucere potest.*

ical men. People would appeal to the feeling of the masses — to the mother on behalf of the body of her child, the son on behalf of the dear remains of his parents. It would be proved that the dismembering of human bodies is injurious to morals and opposed to Christianity. It would be shown that the anatomy of man is useless for the treatment of disease; and perhaps there would be found ignorant or timid or egotistical medical men, who would come forth as witnesses against science. The mildest of our opponents would perhaps propose to us the compromise, that we should again make the dissection of animals the foundation of instruction. In short, we should be thrown back to the time before Mondini, before Erasistratus.

Such thoughts are by no means the productions of an alarmed fancy. The study of history teaches us sufficiently that victorious fanaticism knows no limits. It desires to heap to the full the measure of its victories; and, even when the leaders are contented, the irritated masses press on to obtain the whole results. It is, indeed, not at all necessary for us to go back to antiquity in order to bring before our eyes the condition of such minds. In no country of modern time are there wanting examples which are recognizable by the eye; for, along with the societies against "scientific tormentors of animals," there exist everywhere, but mostly in a more unassuming form, brotherhoods and associations of all kinds, which labor most zealously against the scientific examination of dead bodies. It needs only an impassioned and exciting agitation, such as is now going on against the "torture-chambers of science," to denounce to popular indignation the dissecting-rooms as places where the youths under instruction are made barbarous. Whoever undertakes, with the same extravagant fancy as is now used in delineating the physiological laboratory, to describe the post mortem examination of a man, or an anatomical theatre, will not fail to have readers, who will turn away with horror and amazement at the misdeeds of anatomists.

In vain will an appeal be made to the fact that not one single school of medicine has existed, which has, without a fundamental knowledge of anatomy, established lasting advances in the science or the art of healing. The homeopaths and the so-called nature-doctors (*Naturärzte*), who indeed are already on the scene to strengthen the ranks of the antivivisectionists, will step forth and praise their results. Skepticism, which from time to time grasps about even in medical circles, and which only too easily finds there followers who have in vain called on medical aid for themselves or their belongings — it will scornfully point out how often the physician is powerless against disease. Therapeutics will be thrown aside as useless lumber; and it will be pointed out to us, as is now already done in the petitions of the societies for the protection of animals, that therapy is to be replaced by hygiene, the treatment of individual patients by general measures of public sanitation. And the attempt will then be made to excite the belief, that prophylaxis can exist without anatomy or experiments on animals.

In so large an assembly of medical men as this is, a glance at those present teaches in how many special directions the medicine of to-day has gone. Not every one of these directions is in like measure and as constantly in want of all the means of inquiry and scientific preparation, which are indispensable to cure disease as a whole. Hence, from time to time, a perceptible

one-sidedness becomes manifest in certain of these special arrangements. One believes in his own sufficiency, and looks with indifference, sometimes with a kind of polite contempt, on the rest of medicine. Even the truly scientific studies are not exempt from such one-sidedness; on the contrary, human pride, the tendency to overestimation of one's self, prevail more readily in these than in partial disciplines. We ourselves have seen that organic chemistry, by a most partial use of a very moderate store of knowledge, has made the attempt — and, indeed, not without some temporary result — to prescribe its laws to medicine; and that numerous practical physicians, unmindful of the history of our science, have in fact sought safety in a new kind of iatro-chemistry. Yes, I have a very lively remembrance of the fact that, when I myself was entering on the scientific career, the hope of giving a purely physical aspect to biology was so powerful, that every attempt at morphological study was treated as something antiqua ed.

We have not allowed ourselves to be prevented by this from carrying on anatomical research with every exertion; and we are now in the happy position of seeing it everywhere acknowledged, that every advance in minute anatomy sees behind it an advance in physiological knowledge. Physiologists themselves are more and more becoming also histologists. No one, however, must say that physiology is becoming totally dissolved in histology. No attempt must be made to replace one special subject by another. What is necessary to all branches of medical science in general, is the *knowledge of life*. But this can as little be attained by a simple external examination of the living, as by a partial investigation of the dead. It can be reached by no single study or specialty; it is much rather the collective result of the cultivation of all individual branches of science.

What is to be attained by a mere external examination of the living body has been thoroughly taught by the older medicine. For centuries, sick and healthy have been observed with assiduous diligence, and in fact most valuable material has been collected in the most ingenious manner; but, on the whole, no advance has been made beyond "symptoms." What was perceived were the signs of something internal which was not perceived — indeed, the possible perception of which was hitherto doubted. Life itself stood as it were outside observation; it was only a subject of speculation. Intellectual formulæ were laid down, spiritualistic or materialistic, according to the general tendency of the mind of the individual or of the time; but all agreed in the conviction, that life itself is a transcendental and metaphysical problem. For the practical physician, knowledge that was founded in fact began with symptomatology; for disease as such was apparently not less transcendental than life itself, whose antitype it constituted.

How has it now come to pass that symptomatology has entirely lost the high position in which it still stood little less than a generation ago, to such an extent that in most universities it is no more taught as a specialty? Have symptoms no more any importance for the physician? Can a diagnosis be made without a knowledge of symptoms? Certainly not. But, for the scientific physician, the symptoms are no more the expression of a hidden power, recognizable only in its outer workings: he searches for this power itself, and endeavors to find where it is seated, in the hope of ex-

ploring even the nature of its seat. Hence, the first question of the pathologist and of the biologist in general is, Where? That is the anatomical question. No matter whether we endeavor to ascertain the place of the disease or of life with the anatomical knife or only with the eye or the hand; whether we dissect or only observe, the method of investigation is always anatomical. For this reason the thoroughly logical founder of pathological anatomy named his fundamental book *De Sedibus Morborum*, and hence this book became the starting-point of a movement which, in a few decades, has changed the entire aspect of science.

This change has been carried out to the greatest extent in ophthalmic surgery. Who could limit himself to perceiving that modern ophthalmology has scarcely a single point of similarity with that of the last century? Who contents himself with the symptom of amaurosis? Who despairs of recognizing in it the existence of glaucoma? Every ophthalmic surgeon has in his hands the means of studying the thing itself, and not merely its signs. Even the antivivisectionists acknowledge that ophthalmology is a study that is capable of effecting something. But they forget that every organ of the body is not so favorably placed and arranged for the observation of its inner processes as is the eyeball. Since the wonderful discovery of the ophthalmoscope, anatomical analysis, even without the use of the knife, has become capable of penetrating so far into the individually remote that we can immediately observe and study by themselves the smallest features of the fundus oculi, even, indeed, its single cells, or groups of cells, just as in an artificial preparation of an eye that has been excised. But it must not be forgotten that long anatomical and physiological studies have been a necessary preliminary to the interpretation of that which is now so easily perceived. The structure, arrangement, and function of each single part had first to be laboriously established before it was possible, by a transitory glance at the altered tissue, to recognize what is especially changed; and no medical man will attain to a true comprehension of the essence of these changes if he have not previously learned to recognize most accurately the anatomical and physiological nature, and the possible pathological changes, of the individual constituent parts of the eye.

They speak lightly who object to us that not all the branches of medicine stand on the same height with ophthalmology. That will never be the case. Just as it is easier to explore the sea in its depths than the solid land, so will the most transparent organ of the body always be the most convenient place for medical diagnosis and treatment. While it is possible to observe without difficulty a cysticercus in the hinder part of the retina, one will always be taught to bring a cysticercus of muscle or a trichina in a patient to light by vivisection. Never can it be required that every medical specialty should altogether equal ophthalmology in security of treatment and diagnosis; but any measure of success can only be sought in the use of the ophthalmological method in a corresponding manner in the other special departments. This method, however, is anatomical, or, as it has otherwise been expressed, localizing.

With this we have reached the point which denotes the boundary between ancient and modern medicine. *The principle of modern medicine is localization.* To those who still constantly ask of what use modern science has been to practical medicine, we can simply

point out that every branch of medical practice has accommodated itself to the principle of localization, not only in pathology, but also in therapeutics, and that thereby the greatest benefit has accrued to the sick. It is quite superfluous to seek out single examples in order to show what profit the new knowledge has brought. Such examples are abundant. But we do not require them, for we can point to the general character of modern medicine. All those studies which already at an earlier period had a natural tendency to localization, such as special surgery and dermatology, have in this way been raised to their present state of perfection. These, however, which have retained from the old humoral pathology a tendency to the establishment of generalizing formulae, gradually renounce the favorite tradition; and the fact is more and more comprehended that generalization in truth is nothing else than *multiplication of foci*, and that the cure of a so-called general disease signifies just as much as the eradication of a single focus. That was in fact a reform in head and limbs, and he who has not grasped it ought not to say that he has consciously followed the progress of science.

The notion of the general validity of the doctrine of the localization of disease and of the multiplication of foci of disease in the same individual, stands, as was often objected to me in the beginning of my career as a teacher, in strict opposition to the idea of the *unity of disease*, or, as it is expressed in customary language, to the *ens morbi*. My former colleagues still retained large portions of this idea; they believed that the practical physician entered into arbitrary, and therefore dangerous, speculations, when, in the presence of a single case of disease, he assumed the disease to be a plurality. To me it seems rather the reverse; that the physician enters on a fruitless project (*schematismus*), and one dangerous to his patients, if he suppose each individual case of disease to correspond to the opinion of his school or his own private view, and calculate his prognosis and treatment thereby. Meanwhile, these considerations, derived from medical practice, on the *utility* of a certain way of perceiving disease, can lead to no decision as to its *truth*, and yet at this result only is it possible to arrive. How shall we establish it?

All the world is at one on this point, that disease presupposes life. In a dead body there is no disease. With death life and disease disappear simultaneously. This consideration led the older physicians to assume disease to be a self-living or even animated essence, which took its place in the body along with the vital principle. Many went so far as to define disease as a combat between two contending principles, the innate life and an intrusive foreign body. But all came back to life as a preliminary condition of disease. The view was first lost in the old Layden school; from Boerhaave emanated the dogma, which his pupil Gaubius placed at the head of his long used *Handbook of General Pathology*, the first written on the subject: *Morbus est vita prater naturam*. Disease is life itself; or, to speak more correctly, it is a portion of life.

This assumption displaced the unfortunate dualism which had so long dominated medicine; or, at least, it ought to have displaced this dualism between life and disease. If, nevertheless, it has not completely done this, and if more than a century has been required to break up the still constantly existing dissonance, the reason lies in the difficulty of finding a satisfactory conception of life. And here the question must not be

passed by, Where has life its special seat? *Ubi sedes vite?* John Hunter went back to the ancient view, already expressed in the Mosaic formula: "The life of the body is in its blood." Flourens believed that he had found the seat of life, the *ædud vital*, in the central nervous system, in the medulla oblongata. The one, like the other, found himself obliged to institute experiments on living animals for the investigation of this difficult question. Therewith the experimental method in the more strict sense began to pass into the practice of pathologists. Vivisection became a regular aid to research.

Certainly the consideration that a knowledge of life can only be obtained on the living being was long present. Beyond doubt, it was already formed in antiquity. But it is difficult to determine with accuracy the time when it first became practically active. Uncertain statements only on the subject are available. Zacharias Sylvius, a physician of Rotterdam, who wrote the preface to the Dutch edition of Harvey's *Exercitationes*, calls to mind the tale of Democritus, whom the Abderites regarded as insane, because they saw him constantly engaged in vivisection; when, however, the great Hippocrates was sent for to cure him, he fully recognized the value of his proceedings, and declared that all the Abderites were lunatics, and that Democritus alone was sane.¹ Probably this story has been narrated at the expense of the good Abderites; but it still shows that vivisection already "lay in the air." I will not attempt to decide whether it is true that the teachers in the Alexandrian school actually availed themselves of the permission of their king to dissect criminals. The only conclusion which I can derive from these tales is, that researches on animals must surely have at that time been already practiced. For whoever reflects on the vivisection of men, must acknowledge that, especially at a time when the anatomy of animals formed the foundation of medical study, vivisection had certainly been previously done on animals. In the school of the empirics, which proceeded from that of Alexandria, and in which necropsy was taught as the chief means of knowledge, experiment also appears as having a recognized claim. Only it is not evident to what extent this research on living animals was carried on.

In fact, the first great and distinctive example of successful vivisection which the history of medicine knows, is that of William Harvey. The foundation of the doctrine of the circulation, which in the main was experimental, has radically changed the whole direction of the thoughts of physicians. Had we this one example alone, it would be sufficient to prove brilliantly the utility, yea, the indispensability, of vivisection. Never has a dogma firmly established by the tradition of centuries and every kind of authority, which in truth formed the central point of a powerful and generally acknowledged system, been annihilated with such a headlong downfall. In complete recognition of the importance of such a man, Albert von Haller said that Harvey's name was the second in medicine, that of Hippocrates being the first. But it was a difficult step, to advance a new and unheard of doctrine which

interfered with science in so revolutionary a manner. Having hesitated long whether he should publish his discovery; and when he at last carried his resolution into effect, the great vivisector cried: "*Utenunque sit, jam jaeta est alca, spes mea in amantium veritatis et doctorum animorum candore sita.*"²

It is certainly due, even in the present day, to the purity of a truth-loving and cultivated mind, to exonerate Harvey from the reproach of heartlessness, perhaps of brutality, of which our antivivisectors are so liberal. His new knowledge had cost the lives of many animals; he started, as he himself says, "*ex vivorum (experienti causa) dissectione, arteriarum apertione disquisitioneque multimoda.*" And yet that was the least thing with which he was reproached; even kings at that time were so little tender-hearted, or, I may say, with an opponent, were so brutalized, that King Charles I. found pleasure in seeing the experiments of his body-physician.

On the other hand, after Malpighi had, still in the same century, demonstrated the flow of blood in the capillaries of living animals, and after our century has added the knowledge of the existence of an actual capillary wall, the doctrine of the circulation appears so self-evident, it has so thoroughly entered into the ideas of all, that it already requires a peculiarly trained mind to comprehend the opinion of the older physicians on the local relations of the current of the blood. The widely comprehensive doctrine of inflammation and new growth, within which nearly the greater part of practical cases occur, was founded on experiments on the capillary circulation; not less so was the doctrine of the cure of local diseased processes of most varied kinds.

Even the worst opponents of vivisection recognize Harvey's services. But, say they, since then, nothing more of importance has been accomplished by vivisection. They do not know that it is precisely that department of the doctrine of the process of the circulation which embraces the vital properties of the organs of circulation, which is entirely unmentioned by Harvey.

On what does the activity of the heart depend? What influence do the vessels exert on the propulsion and distribution of the blood? What share falls to the arteries, what to the veins, what to the capillaries? All these questions are of the highest practical importance, and none of them can be investigated otherwise than by experiments on animals. But Harvey could not attack these questions, because in his time minute anatomy was not yet developed. Who knew anything of the nerves of the heart, or of the vessels? Who had any notion as to the participation in the manifestations of the action of the heart and blood-vessels, on the part of the nerves, which supply the parietal structures, especially the fine muscles?

An interval of two centuries again intervened, before Edward Weber, by experiment on the vagus nerve in a living animal, first revealed the mystery of the innervation of the heart; and this, again, in a quite unexpected and unprecedented manner; and before our now so much abused friend Claude Bernard likewise showed on a living animal the influence of the sympathetic nerve on the vessels of the head and neck.

Now for the first time, and through numerous other experiments which have tended to this end, we understand the circulation in its special characters. The

¹ Harvey *Exercit. anat.* Roterod. 1671. Prefatio: Democritus solertissimus operum naturæ perscrutator, cum assidue secundis animalibus occuparetur, existimatus fuit insanus ab Abderitis; qui miserati sortem hominis advocarunt Hippocratem, ut illi medicum faceret mentemque alienatam restitueret. Rogatus decurrit et offendit Democritum animalia secantem, quo spectaculo mirum in modum oblectatus, omnes Abderitas insanire pronuntiavit, solum sapere Democritum.

² Loc. Cit., page 81.

pulse, that so highly treasured object of the old symptomatology, allows itself to be interpreted. It is to us no longer the sign of this or that disease, but the sign of the existence or non-existence of certain activities, of strength or weakness, of irritation or relaxation of certain tissues. Nor for the first time we can understand in its individual peculiarities the action of the heart itself and the operation on it of certain substances—for example—cardiac poisons; and it is not almost alone the department of diseases of the valves, to which alone, and with a scorn that cannot be rightly understood, the antivivisectors point on account of their incurability, but also the department of febrile diseases, which we are in a position to survey as well with regard to their symptoms as to their nature and their results.

The length of the interval of time between Harvey and the more recent experimenters on the innervation of the vascular apparatus is explained by the circumstance, that in that intermediate time two entirely new studies had to be created, to both of which the discovery of the circulation was an impulse and a preliminary condition. I mean physiology and general pathology; thus, indeed, both these studies which are to be regarded as the chief support of the experimental method, and which it was originally the custom to comprise under the name of "Institutiones Medice." Hermann Boerhaave had, in his professorship, combined them, and, indeed, had even united them with practical medicine; under his pupils the division of labor commenced, and the formal separation of the studies. Haller was the special creator of physiology. His experiments went first in the direction of exploring the vital properties of individual parts of the body, of single tissues, as would now be said. Among these properties, following the distinguished Glisson, a man, it seems to me, not even now sufficiently honored in his country, he assigned a prominent place to irritability. It would lead me too far, if I in this place desired to attempt to show forth individually these memorable researches, the comprehension of which was rendered extremely difficult by the then not yet sufficiently complete explanation of the notions "irritability" and "contractility." For our purpose, it is sufficient to point out that here for the first time nerve and muscle, the two most highly developed and thereby most energetic portions of the animal body, were made the subjects of experiment with regard to their special forms of activity. Contraction and sensibility appear as the special signs of living activity. Therewith the question of the basis of living activity was so nearly approached, that Gaubius, who at the same time laid the foundations of general pathology, indicated the vital force as the source of contraction, without going further.¹

From these beginnings was developed, at first in a very obscure and equally unprofitable manner, especially clouded by speculative vitalism, the doctrine of life in its modern form. It has required much longer labors, mostly experimental, to arrive at a great and practical result in spite of all deviations. From the conception of irritability, originally created by Glisson, that of contractility has gradually become separate; and the contrast in which Haller placed irritability and sensibility with regard to each other has been dissolved, by the fact that contractility and sensibility are regarded

as two special forms of expression of life connected with various elements, and are subordinated to irritability as the general expression. In this sense, irritability and vitality are nearly identical. Both are properties of tissue, and as such directly or indirectly accessible to treatment and experiment.

In fact, experimentation is now rather directed to the tissue itself. Galvani's discovery of electric contractions, the labors of Alexander von Humboldt on irritated muscle and nerve-fibre, and many other contemporaneous researches, afford evidence of the changed direction in which the new biology labored. More and more sank down the mysticism of the spirits of life and of disease, the speculation as to an individual vital force; and from generation to generation medicine assumed more and more the character of a real natural science. The obscurity which had dominated especially the nervous system, disappeared under the common labors of anatomists and experimenters; and especially since Charles Bell taught the difference of the nerves hitherto considered as similar in nature, and thereby opened the road to research on the special importance and power of the single divisions of the central nervous system, one work after another has appeared, which has diffused new light on this difficult and complicated subject. It is impossible to go through all these works on this occasion, and it would be superfluous in an assembly of such accomplished men, many of whom have themselves labored in this glorious work.

I will now only briefly point out that among these labors a constantly clearer and more triumphant idea has advanced, which in its beginnings reaches far back into past time, namely, the idea of the proper life (*vita propria*) of the tissues. Every new form of experiment which is devised renders new parts accessible to scientific examination, and with each step in advance we become more clearly convinced that life, regarded as a great unit in the established sense, is a pure fiction, arising from the observation that in the hierarchical organization of the human body certain organs attain so elaborate a structure, and therewith so great importance, that they with complete right merit the name of vital organs. And as among these organs the medulla oblongata possesses the greatest importance, it is easily comprehensible that the idea should arise that it might really be the seat of life. But we know now that life is a collective functional action of all parts of the higher or vital as well as of the lower and less important; and that there is no one seat of life, but that every true elementary part, especially every cell, is a seat of life. In biological research also, as well as in pathological, we have arrived at a multiplication of foci. Of course the number of vital foci is much greater than that of foci of disease can ever be; and hence disease and life, or, to speak more accurately, diseased and healthy life can very well coexist in the same organism; always, however, so that disease signifies a reduction, a *minus* of healthy life. By this research we have even rediscovered the long-lost essence of disease, not, indeed, in a spiritualistic form, but as a quite material *ens*, a genuine incarnate thing—the altered cell.

Has all now produced advantage? Was it worth the trouble to inflict pain on so many animals? to kill so many animals? Is there a really justifiable claim for allowing the experimental method to proceed still further? We can answer all these questions confidently in the affirmative. Not every experiment on

¹ Gaubius, loc. cit. Path. Med., page 71. "Vis vitalis solidi est, quæ ab affectione irritationis se contrahit."

animals has results as great as that of Galvani, results which have not merely led to a new and effective method of treating disease — electrotherapy; which have not only disclosed a large new territory of vital processes, but have supplied the first preliminary condition for an incalculable number of the most important technical arrangements, the knowledge of the natural course of events. But galvanism might yet appear to limited and timid heads as an instructive and refreshing play, for the reason that not every result of true observation of nature is usually brought forward at once, and that nevertheless it may be of the highest practical value. The cellular theory and the proof of the *vita propria seu cellularis* are in themselves very abstruse things, and no one can cure patients by their means without understanding something further. And yet they have become the foundation, yea, in a certain measure the security, for localizing therapeutics, and they will surely become more so from day to day, when first *materia medica* in its wider extent shall have gone on the way which toxicology has already for a long time followed in a manner so rich in results.

How, then, can a great result to the science of healing be expected if research in animals be cut off? For a long time no remedy has been more rapidly recognized, or more extensively used, than chloral, the effects of which were discovered and established experimentally by Herr O. Liebreich in my laboratory. How would it have been possible to know how to ascertain those effects without experiments on animals? The animals' friends say to us, "Then try the new medicine on yourselves!" They refer us to the provings of medicines by the homeopaths. But, quite independently of the fact that the provings of the homeopaths have not taught us to recognize one single new remedy which can be compared even at a distance with chloral, and that these provings, even in regard to already known remedies, do not in the least correspond to scientific investigations; that thus they cannot be altogether regarded as an original example — one will yet not be able to earnestly desire that very different, possibly poisonous bodies, should be made the subject of self-experimentation by physicians or other men. This kind of morality, which forbids experiment on animals, and counsels experiment on one's own life or on sick men, misses, in fact, the first foundations of intelligent examination.

The proof of the great importance of hygiene and prophylaxis is rather superfluous. If any class of men has been active in this direction it is surely medical men. Never has there been a want of zealous hygienists among them; and when a great problem of prophylaxis was to be solved one might be sure of finding medical men engaged in the work. We are so accustomed to this obligation that we always regard hygiene and prophylaxis as belonging to medicine, and to no other science. But it is empty talk when it is said that prophylaxis will render therapeutics — yea, even in a certain degree, medicine — superfluous. The arrangement of this imperfect world is such that there surely will be sick as long as men exist; and we are not afraid because of the threat that there will be no further need of us. Not even through the assistance of hygiene will people be able to do without us; and still less without experiment on animals. Will even the hygienists be condemned to test the various "causes," cold and warmth, dryness and moisture, dust and noxious gases, micrococci and bacteria on their

own persons, in order that they may from such self-observations determine their effects, and formulate laws? Intelligent governments will comprehend that it would be an act of madness to sacrifice human life merely because it occurs to a small number of persons that it is criminal to sacrifice the lives of animals. Medical men are already more exposed in epidemics of all kinds, in the performance of their duties in hospitals, in the country, in their nocturnal visits to the sick, in operations and necropsies, than any other class of the community, as a rule; and it requires all the blindness of the animal fanatics to require also of them that they should test on their own bodies the remedial, or poisonous, or indifferent action of unknown substances, or that they should determine the limit of permissible doses by observations made on themselves.

In the name of humanity, of morality, of religion, the suppression of experiment on animals is demanded. For, in fact, it is not merely vivisection that is in question, but experiment on animals; that is, the experimental method in general. When the term vivisection is used, it is made to include in like manner all painful actions in which there is no cutting; indeed, to prevent any misconception, not only physiological, but also pathological and pharmacological, experiments are expressly included. *The criterion is pain. Everything by which, in the way of experiment, pain is inflicted on an animal is torture of animals*, and so far immoral, and contrary to religion. With this definition of torture of animals, it might be possible to arrive at exceptional results by applying it to other callings or men. The dog-fanciers, who in the rearing of their dogs often use, or cause to be used, methods full of torture and painful chastisement would readily come into great danger. The improvement of horses for certain purposes would have to be entirely put down. A great part of our domestic animals would have to remain untrained, so that pain might be spared to them. We should perhaps arrive at conditions similar to those produced by the wild dogs in Turkey.

Individual antivivisectors are at least so far consistent that they would see the slaughter of animals also forbidden. From the vegetarian standpoint, the opposition gains a kind of systematic aspect. Thus Herr von Seefeld¹ demands a vegetable diet and the prohibition of vivisectors; but as he, as a vegetarian, has no need of flesh he is strongly inclined to make still further concessions. Thus he rejects hunting for the purpose of pleasure, but cannot altogether dispense with it as a means of defending life. Others go still further, and sacrifice also war. The principle can scarcely be denied that death is worse than torture. There could scarcely be a criminal code which punishes the premeditated killing of a man less severely than the torture of a man. Not without reason is it alleged that a man who still remains alive after his misdeeds, may recover and attain to a complete or entire enjoyment of life. Grounds of mitigation in cases of murder and manslaughter are allowed also to men; but, as a foundation, the extremest injury which can be inflicted on man is always and everywhere the most severely punished.

As regards animals, the antivivisectors, on the contrary, consider torture to be worse than death. Although they reject every torturing or painful method of death, even for cattle, they without the slightest con-

¹ Alfred von Seefeld. *Altes und Neues über die vegeterianische Lebensweise*. Hanover. 1889.

sideration cause animals, even highly organized ones, to be slaughtered or killed, not only for eating, but also for other purely subjective reasons. They go, indeed, so far as to demand that an animal which has survived vivisection shall be killed, although it might possibly still enjoy a long and happy life. Is there any logic in this, or any morality? How? may we have the right to kill an animal on any ground of public utility, to eat its flesh, to sell its skin, to pound its bones to manure for the field? and are we not to have the right of subjecting it to scientific research, which we institute on entirely ideal grounds, or on the grounds of the public weal, in which we even perhaps run the risk of becoming diseased? It will be difficult to assume that we institute researches on glanders or splenic fever for pleasure, or to pass away time, or without knowledge of the great danger of inoculation. Whoever allows himself the right to kill animals has no right to forbid physicians to vivisect animals for experimental purposes, or to undertake painful operations of any other kind.

Of course, we cannot desire that the misuse of this right should escape punishment. For it is with such an abuse, not with the production of pain, that torture of animals first comes into operation. Were every production of pain in itself an act of torture, punishment ought to be inflicted on a veterinary surgeon when he operates on a sick horse for the purpose of curing it. Culpable torture of animals lies before us, when pain is inflicted on an animal in a useless manner, and without purpose. Hence nothing can be said against the view that every experimenter should be subject to official inspection, but surely this does not require a society for the protection of animals. He who has a greater interest in domestic animals than in science, that is, in the knowledge of truth, is not qualified to be an official controller of scientific affairs. To what would it lead, if an experimenter, who had commenced his experiment in good faith, had perhaps to answer to some layman during the experiment, or to a magistrate afterwards, the charge that he had not selected some other method, or some other instruments, or perhaps some other experiment.

Not here is no question of objective right. So long as perfect liberty is left to every possessor of animals to kill his animals, be they wild or tame, at any time, and according to his own judgment, so long must it also be permitted that, for scientific ends, and thus on purely internal grounds, experiments should be made on living animals. But the necessity of such experiments can naturally only be decided by the inquirer himself; as to the choice of place, time, the admission of strangers, he may be required to communicate with the inspector; but the carrying out of the experiment must remain in his own hands. So we understand the expression of the freedom of science.

What is objected to is, that it is the outraged feelings of the possessor of horses, pet dogs, and parlor cats, that excite him to the belief that the same thing may happen to his beloved animals as to the animals in the learned institute. We can sympathize with him. We would force no one to deliver to us his favorites, nor would we steal them. Were either of the two to occur, probably in every country the intervention of the magistrate would be called on with effect. But we also require that the disposal of the life and maintenance of those animals which have come into our possession in a legitimate way, should not be lessened

to us, and that we should not be considered or declared to be *à priori* rough, void of moral feeling, and barbarians standing almost on the threshold of crime. The evidence that moral earnestness is failing in modern medical circles is nowhere afforded. The reproach that Christianity is imperiled by vivisection, is worthy of Abdera. The assertion that the medical youth are inevitably "brutalized" by dissection and vivisection, is, as usual, snatched from the air; as it is also a calumny that the vivisection teachers have suffered injury to their morality.

At least, however, there is no ground to fear for science itself. To it is applicable what Bacon said of the sun: "*Palatia et cloacas ingreditur, neque tamen polluitur.*"

AN ADDRESS ON VACCINATION IN RELATION TO CHICKEN CHOLERA AND SPLENIC FEVER.¹

BY M. PASTEUR, PARIS.

GENTLEMEN,—I had no intention of addressing this admirable Congress, which brings together the most eminent medical men in the world, and the great success of which does so much credit to its principal organizer, Mr. MacCormac. The good-will of your esteemed president has decided otherwise. How could one, in fact, resist the sympathetic words of that eminent man whose goodness of heart is associated in no small degree with great oratorical ability? Two motives have brought me to London. The first was to gain instruction, to profit by your learned discussions; and the second was to ascertain the place now occupied in medicine and surgery by the germ theory. Certainly I shall return to Paris well satisfied. During the past week I have learned much. I carry away with me the conviction that the English people is a great people; and as for the influence of the new doctrine, I have been not only struck by the progress it has made, but by its triumph. I should be guilty of ingratitude and of false modesty, if I did not accept the welcome I have received among you and in English society as a mark of homage paid to my labors during the past five and twenty years upon the nature of ferments—their life and their nutrition, their preparation in a pure state by the introduction of organisms (*ensemencement*) under natural and artificial conditions—labors which have established the principles and the methods of *microbie* (microbism), if the expression is allowable. Your cordial welcome has revived within me the lively feeling of satisfaction I experienced, when your great surgeon Lister declared that my publication in 1857 on milk-fermentation had inspired him with his first ideas on his valuable surgical method. You have reawakened the pleasure I felt when our eminent physician Dr. Davaine declared that his labors upon *charbon* (splenic fever or malignant pustules) had been suggested by my studies on butyric fermentation and the vibrio which is characteristic of it.

Gentlemen, I am happy to be able to thank you by bringing to your notice a new advance in the study of micro-organisms as applied to the prevention of transmissible diseases—diseases which for the most part are fraught with terrible consequences, both for man and domestic animals. The subject of my communication is inoculation in relation to chicken cholera and splenic fever, and a statement of the method by which

¹ This translation originally appeared in the London Times.

we have arrived at these results — a method the fruitfulness of which inspires me with boundless anticipations.

Before discussing the question of splenic fever vaccine, which is the most important, permit me to recall the results of my investigations of chicken cholera. It is through this inquiry that new and highly important principles have been introduced into science concerning the virus or contagious quality of transmissible diseases. More than once in what I am about to say I shall employ the expression virus-culture, as formerly, in my investigations on fermentation, I used the expressions, the culture of milk-ferment, the culture of the butyric vibrio, etc. Let us take, then, a fowl which is about to die of chicken cholera, and let us dip the end of a delicate glass rod in the blood of the fowl with the usual precautions, upon which I need not here dwell. Let us then touch with this charged point some *bouillon de poule*, very clear, but first of all rendered sterile under a temperature of about 115° cent. (239° Fahr.) and under conditions in which neither the outer air nor the vases employed can introduce exterior germs — those germs which are in the air or on the surface of all objects. In a short time, if the culture vase be placed in a temperature of 25° to 35° cent. (77° to 95° Fahr.) you will see the liquid become turbid and full of tiny micro-organisms, shaped like the figure 8, but often so small that under a high magnifying power they appear like points. Take from this vase a drop as small as you please, no more than can be carried on the point of a glass rod as sharp as a needle, and touch with this point a fresh quantity of sterilized *bouillon de poule*, placed in a second vase, and the same phenomenon is produced. You deal in the same way with a third culture vase, with a fourth, and so on to a hundred or even a thousand, and invariably within a few hours the culture liquid becomes turbid and filled with the same minute organisms. At the end of two or three days' exposure to a temperature of about 30° cent. (86° Fahr.), the thickness of the liquid disappears, and a sediment is formed at the bottom of the vase. This signifies that the development of the minute organism has ceased — in other words, all the little points which caused the turbid appearance of the liquid have fallen to the bottom of the vase; and things will remain in this condition for a longer or shorter time, for months even, without either the liquid or the deposit undergoing any visible modification, inasmuch as we have taken care to exclude the germs of the atmosphere. A little stopper of cotton sifts the air which enters or issues from the vase through changes of temperature.

Let us take one of our series of culture preparations — the hundredth or the thousandth, for instance — and compare it in respect to its virulence with the blood of a fowl which has died of cholera; in other words, let us inoculate under the skin ten fowls, for instance, each separately with a tiny drop of infectious blood and ten others with a similar quantity of the liquid in which the deposit has first been shaken up. Strange to say, the latter ten fowls will die as quickly and with the same symptoms as the former ten: the blood of all will be found to contain after death the same minute infectious organisms. This equality, so to speak, in the virulence both of the culture preparation and of the blood is due to an apparently trivial circumstance. I have made a hundred culture preparations — at least, I have understood that this was done — without leav-

ing any considerable interval between the impregnations. Well, here we have the cause of the equality in the virulence.

Let us now repeat exactly our successive cultures with this single difference, that we pass from one culture to that which follows it, from the hundredth to, say, the hundred and first, at intervals of a fortnight, a month, two months, three months, or ten months. — If, now, we compare the virulence of the successive cultures, a great change will be observed. It will be readily seen from an inoculation of a series of ten fowls, that the virulence of one culture differs from that of the blood and from that of a preceding culture, when a sufficiently long interval elapses between the impregnation of one culture with the micro-organism of the preceding. More than that, we may recognize by this mode of observation that it is possible to prepare cultures of varying degrees of virulence. One preparation will kill eight fowls out of ten, another five out of ten, another one out of ten, another none at all, although the micro-organism may still be cultivated. In fact, what is no less strange, if you take each of these cultures of attenuated virulence at a point of departure in the preparation of successive cultures and without appreciable interval in the impregnation, the whole series of these cultures will reproduce the attenuated virulence of that which has served as the starting point. Similarly, where the virulence is null, it produces no effect.

How, then, it may be asked, are the effects of these attenuated virulences revealed in the fowls? They are revealed by a local disorder, by a morbid modification more or less profound in a muscle, if it is a muscle which has been inoculated with the virus. The muscle is filled with micro-organisms, which are easily recognized because the attenuated ones have almost the bulk, the form, and the appearance of the most virulent. But why is not the local disorder followed by death? For the moment, let us answer by a statement of facts. They are these: the local disorder ceases of itself more or less speedily, the micro-organism is absorbed and digested, if one may say so, and little by little the muscle regains its normal condition. Then the disease has disappeared. When we inoculate with the micro-organism the virulence of which is null there is not even local disorder: the *natura medicatrix* carries it off at once, and here, indeed, we see the influence of the resistance of life, since this micro-organism, the virulence of which is null, multiplies itself.

A little further, and we touch the principle of vaccination. When the fowls have been rendered sufficiently ill by the attenuated virus which the vital resistance has arrested in its development, they will, when inoculated with virulent virus, suffer no evil effects, or only effects of a passing character. In fact, they no longer die from the mortal virus, and for a time sufficiently long, which in some cases may exceed a year, chicken cholera cannot touch them, especially under the ordinary conditions of contagion which exist in fowl-houses. At this critical point of our manipulation — that is to say, in this interval of time which we have placed between two cultures, and which causes the attenuation, what occurs? I shall show you that in this interval the agent, which intervenes, is the oxygen of the air. Nothing more easily admits of proof. Let us produce a culture in a tube containing very little air, and close this tube with an enameled lamp. The micro-organism in developing itself will speedily

take all the oxygen of the tube and of the liquid, after which it will be perfectly free from contact with oxygen. In this case it does not appear that the micro-organism becomes appreciably attenuated, even after a great lapse of time. The oxygen of the air, then, would seem to be a possible modifying agent of the virulence of the micro-organism of chicken cholera; that is to say, it may modify more or less the facility of its development in the body of animals. May we not be here in presence of a general law applicable to all kinds of virus? What benefits may not be the result? We may hope to discover in this way the vaccine of all virulent diseases; and what is more natural than to begin our investigation of the vaccine of what we in French call *charbon*, what you in England call splenic fever, and what in Russia is known as the Siberian pest, and in Germany as the *Milzbrand*.

In this new investigation, I have had the assistance of two devoted young *savants*, MM. Chamberlain and Roux. At the outset, we were met by a difficulty. Among the inferior organisms all do not resolve themselves into those corpuscle-germs which I was the first to point out as one of the forms of their possible development. Many infectious micro-organisms do not resolve themselves in their cultures into corpuscle-germs. Such is equally the case with beer-yeast, which we do not see develop itself usually in breweries, for instance, except by a sort of fissiparous production. One cell makes two or more which form themselves in wreaths; the cells become detached, and the process recommences. In these cells, real germs are not usually seen. The micro-organism of chicken cholera and many others behave in this way, so much so that the cultures of this micro-organism, although they may last for months without losing their power of fresh cultivation, perish finally like beer-yeast which has exhausted all its aliments. The anthracoid micro-organism in artificial cultures behaves very differently. In the blood of animals, as in cultures, it is found in translucent filaments more or less segmented. This blood or these cultures freely exposed to air, instead of continuing according to the first mode of generation, show at the end of forty-eight hours corpuscle-germs distributed in series more or less regular along the filaments. All around these corpuscles matter is absorbed, as I have represented it formerly in one of the plates of my work on the diseases of silkworms. Little by little all connection between them disappears, and presently they are reduced to nothing more than germ-dust. If you make these corpuscles germinate, the new culture reproduces the virulence peculiar to the thready form which has produced these corpuscles, and this result is seen even after a long exposure of these germs to contact with air. Recently we discovered them in pits in which animals dead of splenic fever had been buried for twelve years, and their culture was as virulent as that from the blood of an animal recently dead.

Here I regret extremely to be obliged to shorten my remarks. I should have had much pleasure in demonstrating that the anthracoid germs in the earth of pits in which animals have been buried are brought to the surface by earthworms, and that in this fact we may find the whole etiology of disease, inasmuch as the animals swallow these germs with their food.

A great difficulty presents itself when we attempt to apply our method of attenuation by the oxygen of the air to the anthracoid micro-organisms. The virulence establishing itself very quickly, often after four-and-

twenty hours in an anthracoid germ which escapes the action of the air, it was impossible to think of discovering the vaccine of splenic fever in the conditions which had yielded that of chicken cholera; but was there, after all, reason to be discouraged? Certainly not. In fact, if you observe closely, you will find that there is no real difference between the mode of the generation of the anthracoid germ by fission and that of chicken cholera. We had, therefore, reason to hope that we might overcome the difficulty which stopped us by endeavoring to prevent the anthracoid micro-organism from producing corpuscle-germs, and to keep it in this condition in contact with oxygen for days, and weeks, and months. The experiment fortunately succeeded. In the ineffective (*neutre*) *bouillon de poule* the anthracoid micro-organism is no longer cultivable at 45° cent. Its culture, however, is easy at 42° or 43° cent., but in these conditions the micro-organism yields no spores. Consequently it is possible to maintain in contact with the pure air at 42° or 43°, a mycelian culture of bacteridia entirely free of germs. Then appear the very remarkable results which follow. In a month or six weeks the culture dies. That is to say, if one impregnates with it fresh *bouillon*, the latter is completely sterile. Up till that time life exists in the vase exposed to air and heat. If we examine the virulence of the culture at the end of two days, four days, six days, eight days, etc., it will be found that long before the death of the culture the micro-organism has lost all virulence, although still cultivable. Before this period it is found that the culture presents a series of attenuated virulences. Everything is similar to what happens in respect to the micro-organism in chicken cholera. Besides, each of these conditions of attenuated virulence may be reproduced by culture; in fact, since the *charbon* does not recur a second time (*ne récidive pas*), each of our attenuated anthracoid micro-organisms constitutes for the superior micro-organism a vaccine—that is to say, a virus capable of producing a milder disease.

Here, then, we have a method of preparing the vaccine of splenic fever. You will see presently the practical importance of this result: but what interests us more particularly is to observe that we have here a proof that we are in possession of a general method of preparing virus vaccine based upon the action of the oxygen and the air—that is to say, of a cosmic force existing everywhere on the surface of the globe. I regret to be unable from want of time to show you that all these attenuated forms of virus may very easily, by a physiological artifice, be made to recover their original maximum virulence. The method I have just explained of obtaining the vaccine of splenic fever was no sooner made known, than it was very extensively employed to prevent the splenic affection. In France, we lose every year by splenic fever animals of the value of 20,000,000 francs. I was asked to give a public demonstration of the results already mentioned. This experiment I may relate in a few words. Fifty sheep were placed at my disposition, of which twenty-five were vaccinated. A fortnight afterwards, the fifty sheep were inoculated with the most virulent anthracoid micro-organism. The twenty-five inoculated sheep resisted the infection; the twenty-five non-inoculated sheep died of splenic fever within fifty hours. Since that time, my energies have been taxed to meet the demands of farmers for supplies of this matter. In the space of fifteen days, we have inoculated in the

department surrounding Paris more than twenty thousand sheep and a large number of cattle and horses.

If I were not pressed for time, I should bring to your notice two other kinds of virus attenuated by similar means. These experiments will be communicated by and by to the public.

I cannot conclude, gentlemen, without expressing the great pleasure I feel at the thought that it is as a member of an International Medical Congress assembled in England that I make known the most recent results of vaccination upon a disease more terrible, perhaps, for domestic animals than small-pox is for man. I have given to vaccination an extension which science, I hope, will accept as a homage paid to the merit, and to the immense services, rendered by one of the greatest men of England, Jenner. What a pleasure for me to do honor to this immortal name in this noble and hospitable city of London!

Recent Literature.

A Manual on Diseases of the Eye and Ear, for the Use of Students and Practitioners, by W. F. MITTENDORF, M. D., etc. New York: G. P. Putnam's Sons. 1881. Pp. 445.

If it be true that he is a benefactor of mankind who has made two blades of grass grow where one grew before, the same cannot be said as to the multiplication of books. It is not a greater number of books that is needed, but better ones. A new book is only of value if it present new facts or new ideas to the reader, or set forth old ones in more attractive or comprehensible style. Judged by this standard the book before us can hardly be regarded as altogether a success.

The author's aim was, he says, to make this book, intended for the elementary study of the eye and ear, as practical and brief as the great importance of the subject would permit; to be as thorough as possible in the description, treatment, and differential diagnosis of those diseases which we are most apt to meet with in general practice. The plan thus outlined is excellent, its execution, unfortunately, not quite so satisfactory.

Three hundred and sixty pages are devoted to the eye, seventy to the ear.

In an elementary work it is of special importance that the language should be clear and distinct; here, however, sentences are frequently carelessly framed: "In the other condition it is generally due to a spasmodic action of the orbicularis, in acute inflammatory actions of the eye, with more or less œdema of the lid, or by a slight irritation of the conjunctiva of old persons with very loose skin." We meet with strange words: "pedicellated;" there are occasional contradictions, thus, under syphilitic ulcerations of the lids we read: "The ulcer spreads rapidly, often destroying a large portion of the lid;" and, two lines below, "There is generally nocturnal pain connected with the disease; its progress is generally slow."

Good wood-cuts are often of great assistance to a proper understanding of the text, particularly for readers unfamiliar with the subject treated of. We find but nine. Two illustrate an operation, and answer their purpose well; one serves to help, or confuse (?) the explanation of the course of the nerve-fibres from the brain to the retina; of the others, though of the simplest, several might easily be more accurate. Chromolithographs, copied from Sichel's Atlas, from Wells'

reproductions from Liebreich, and from Politzer, terminate the volume.

The statement that "exophthalmus can be differentiated from prominent eyes by the fact that an exophthalmus eye projects farther than a straight line drawn from the upper to the lower orbital margin," might well be modified with advantage, nor should we agree with the author that this affection may be due to myopia, to staphyloma of the cornea or sclera, or to hydrophthalmus.

The directions to treat a chalazion by making a crucial incision through the conjunctiva and removing a portion of the projecting points of the crucial incision by scissors we regard as bad surgery, and totally disagree with the advice, "never cut through the integument of the lid even if the tumor is pointing here very strongly."

It may be doubted, perhaps, if it be very practical to describe thirty-three varieties of cataract in an elementary work.

A curious misconception of a theory proposed by Von Graefe, but long generally abandoned, is found on page 292: "It has been claimed that obstruction of the venous circulation, due to compression of the ophthalmic vein, might lead to papillitis, but this is hardly possible, because the central vein of the retina empties directly into the cavernous sinus," etc.

Von Graefe's idea was that compression of the cavernous sinus checked the flow of blood from the ophthalmic vein, and so caused distention of the central vein of the retina, and that neuritis.

It is true that the vena centralis often, or generally, empties directly into the cavernous sinus, as our author states. This, however, would rather support the theory than disprove it, and it was in spite of this fact, and mainly because it was shown that the vena centralis anastomoses freely with the ophthalmic vein, and the latter again with the anterior facial vein, that the theory was given up.

The tick of a watch is said to be the most reliable test of the amount of hearing. "This should be heard by a normal ear at thirty-six inches; if, however, it is heard only at six inches the hearing power is only like $\frac{3}{8}$ or $\frac{1}{2}$." Probably the intelligence of the reader is relied upon for the reflection that all watches do not tick equally loud, yet it would have been better not to have laid down the rule so positively.

There are better text-books to be had.

Die Nerven Schwäche (Neurasthenia) ihre Symptome, Natur, Folgezustände, und Behandlung. Praktisch bearbeitet von GEORG M. BEARD, A. M., M. D. Nach der zweiten Auflage ins Deutsche übertragen und mit einem Vorwort versehen von SAN-RATH DR. M. NEISSER in Breslau, Badearzt in Charlottenbrunn. Leipzig: Verlag von F. C. W. Vogel. 1881. Pp. viii., 178.

This is a very good translation of Dr. Beard's book on Neurasthenia, second edition. The translator has slightly abridged the work by occasionally omitting parts of sentences, but nothing important has been sacrificed. The style of the original has rather been simplified and improved. The preface to the German edition is simply a short statement of the importance of the subject treated, and the expression of a hope that the condition of nervous weakness described may be more readily recognized after reading the work.

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 1, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

MALARIA IN NEW ENGLAND.

THE reappearance of malaria at various places in New England from which it has been absent for many years, and its marked extension of late throughout the lower Connecticut River Valley, are exciting increasing notice and comment. Though the fact seems to be indisputable that this affection is much more frequent and general than formerly, as yet no sufficient explanation of the cause, as far as we are aware, has been offered.

In a recent monthly report of the Connecticut State Board of Health, its secretary states that the malarial wave is gradually extending over the State, and goes on to say that: "The only general features that appear to influence it are the rivers along whose valleys it extends and spreads from right to left with greater frequency in the valleys, and the coast line along which it extends and spreads inland. Dr. Knight, of New Haven, is quoted as saying that it never wholly disappeared from the limestone regions of the lower Housatonic valley. If that be so, then we have the centre from which this recent outbreak may have started. It sometimes advances *per saltum*, that is, skipping certain regions, and on the hill-tops, as well as in the valleys, appears sometimes in one form first, sometimes in another. After a careful personal study of a large area, including the valleys of the Connecticut, Housatonic, and Quinnipiac, wholly or partially, which I hope during the present year to extend over the whole malarial region in this State, I have not yet found a cause for the prime appearance of malarial disease. Such local causes as have been investigated have either originated after the appearance of the disease, or else had been in existence long before. Often local causes have been found which apparently induced a localized epidemic, or the persistency and frequency of the disease, as the clay cut on the course of one of the new railroads near which the cases were vastly more numerous than elsewhere in the neighborhood, and the pestiferous marsh in Durham, in whose immediate vicinity was a localized epidemic of typho-malarial fever, but in both instances the disease was in the neighborhood long before.

"It is pretty generally believed that scarlet fever and typhoid fever depend upon the contagion of a preceding case, and I see no reason to doubt, although a fever very like typhoid is apparently due to filth, and called cesspool fever. In a similar manner malarial diseases depend upon a contagion or germ, whatever it may be, which is not produced by the system of the patient. Just how the germ of the disease, for it may

as well be called that as anything, is produced is unknown. The later manifestations of the disease in New England, with its steady progress to the east and north, irrespective of any of the time-honored theories of its causation, compels a new study and comparison of data. Whether the disease originates in each new location from some local conditions, or is due to some law of diseases we do not yet understand, remains to be proved. It appears to be modified by local conditions such as have been alluded to, and perhaps the type may be thus influenced as well as its frequency and persistency. It must, however, be remembered that because malarial diseases have appeared on a hill-top in Connecticut the age of the dwellers near the Pontine Marshes is not a myth."

The extension of malaria as observed in Connecticut is certainly not usually attendant upon increased population and cultivation. The same tendency has made itself apparent in western Massachusetts, and was, we believe, at one time receiving the attention of the Board of Health of this State.

The subject is certainly worthy of timely and careful investigation, and needs to have more light thrown upon it. If anything can be devised to prevent it, the list of fertile and attractive districts in this country rendered uninhabitable or unhealthy by this insidious poison should not be allowed to grow longer. We should rather hope to put ourselves in a position to reclaim some of those already invaded.

We cannot fail to be reminded by indigenous cases of intermittent fever which have of late presented themselves in Newton, about Fresh Pond, at Cambridge, and in Boston, of interesting quotations from records dating back to the early days of the settlement of this neighborhood, which the curious reader will find in Dr. S. A. Greene's centennial address before the Massachusetts Medical Society.

THE NEW YORK LAW TO PREVENT THE ADULTERATION OF FOOD AND DRUGS.

THE full text of the new law of New York State in relation to the adulteration of food and drugs, which makes it a misdemeanor to manufacture or offer for sale any adulterated article of food or drugs, was published in the JOURNAL of August 14th. It goes into force on this the first day of September, and the State Board of Health have issued a circular to the public in which they announce that eight competent chemists have been appointed for the analysis of the various kinds of goods, and arrangements been made for the collection of samples. The Board requests all who are interested in promoting health by guarding against adulterated and deleterious articles of food and beverages to inquire concerning illegal traffic in such articles, and that whenever any person is cognizant of a case in which there seems to be evidence of injury from their use information should be immediately sent to the office of the Board at Albany, when an investigation of the matter will at once be undertaken. The circular further states that the Board desires the fact to be well understood by the

public that this law originated as a national measure for the protection of the people, as recommended by the National Board of Health and National Board of Trade, and that in the State of New York its administration will be based upon effectual coöperation of the State Board of Health with the people and honest producers and tradesmen, and upon the faithfulness and skill of the Board's carefully selected chemical analysts.

The work of analysis is arranged under eleven heads and groupings, and allotted as follows:—

Animal Food. I. Milk, fresh and condensed. Assigned to Professor Chamiller. II. Butter, dairy and artificial; cheese; lard; olive oil; and fruit essences. Assigned to Professor Caldwell, of Cornell University. III. Canned meats and animal foods; meats, fresh, smoked, salted, canned; extracts and essences of meat and fish; gelatine and isinglass. Assigned to Professor Chester, of Hamilton College.

Vegetable Food. IV. Cereals and the products and accessories of flour and bread foods. Assigned to E. G. Love, Ph. D., New York. V. Canned fruits and vegetables, pickles, preserves, spices, etc. Assigned to Professor Lattimore, of Rochester University. VI. Sugars; syrups; molasses; glucose; confectionery; honey; and soda-water syrups. Assigned to Dr. W. H. Pitt, Buffalo. VII. Tea; coffee; cocoa. Assigned to Professor Lattimore. VIII. Wines; beers; spirits; and cordials. Assigned to F. E. Engelhardt, Ph. D., Syracuse.

Drugs. IX. Crude vegetable and animal drugs. Assigned to Frederick Hoffmann, Ph. D., New York. X. Pharmaceutical chemicals and their preparations. Assigned to Dr. Hoffmann. XI. Organic preparations employed in medicines; cinchona, opium, etc., and their alkaloids; commercial pills, coated and otherwise; ethers and essences. Assigned to Professor Caldwell.

The law is of national rather than merely sectional importance, and its operation will be watched with great interest.

MEDICAL NOTES.

NEW YORK.

—Since the 23d of July there have been seven yellow-fever patients at the Quarantine Hospital, of whom two died, and five were discharged cured. Yellow fever is said to be very prevalent at Havana this summer. During the week ending July 16th fourteen deaths were reported from it; during the week ending July 23d twenty-one deaths, and one hundred and twenty cases were reported; and during the week ending July 30th, thirty-one deaths.

—Dr. Robert R. Mellvain died last week at the age of sixty-eight years from cancer of the stomach, and an autopsy was made by Drs. Frank Hamilton, Willard Parker, and John Messenger. When a young man Dr. Mellvain studied in Paris for a considerable time under Claude Bernard, and after his return to America settled in Ohio, but had lived in New York for a number of years before his death. He

was a very accomplished gentleman, and his memory for dates and statistics was quite extraordinary.

—The quarterly meeting of the State Board of Health was held at the Cataract House, Niagara Falls, on the 10th of August, and the session was mainly devoted to the subject of the suppression of the stench nuisances in the vicinity of New York city, which have so long been an annoyance to the citizens.

—A boy twelve years of age recently died from hydrophobia at the New York Hospital. He was bitten slightly on the hand by a large vagrant dog on the 15th of April last, and the wound was promptly cauterized. His last illness was very brief, lasting only from Sunday to Tuesday, and while he was in the hospital curare was employed without any appreciable effect upon the course of the disease.

Miscellany.

LETTER FROM LONDON. INTERNATIONAL MEDICAL CONGRESS.

LONDON AND SUBURBAN PUBLIC AND PRIVATE HOSPITALITY.—THE LORD MAYOR'S BANQUET.—CONVERSAZIONE AT THE GUILDHALL.—STORED ELECTRICITY.—RECEPTION BY LORD GRANVILLE.—GARDEN PARTY OF THE LONDON SCHOOL OF MEDICINE FOR WOMEN.—GARDEN PARTY OF LADY BURDETT-COUTTS, ETC., ETC.

LONDON, August 6, 1881.

MR EDITOR,—The weather continues perfect, the success, bustle, business, festivity, and labor of the seventh session of the International Congress proceed undiminished. It would be invidious to attempt to record the extent of the hospitality which is so profuse on the present occasion as to defy enumeration. Nevertheless one must notice that the principal officers of the Congress are practically keeping open house in no mean spirit. Breakfasts, luncheons, and dinners have succeeded each other daily in the homes of many of the presidents of sections, as well as in that of the President of the Congress, Sir James Paget, whose hospitality and eloquence have alike upon the present occasion baffled adequate description. Notwithstanding the importance of the business before the various sections, and the earnestness of the workers in them, ample participators have been found to avail themselves of the very many interesting and attractive pleasure trips which have been daily offered to them; excursions to the London Docks, to Messrs. Penus' works, have been specially organized in the most liberal spirit by the principals, whilst this afternoon a special train has conveyed a large number of members to Folkestone to witness the unveiling of Harvey's statue, and to partake of the hospitality of the corporation there. Each day finds numerous invitations for garden parties and river trips to the principal suburban seats of members of the profession, as well as to those of public personages. The Baroness Burdett-Coutts this afternoon is giving a large garden party at her picturesque estate, Holly Town, Highgate, and to-night Lord Granville, the present Foreign Minister, entertains the leading foreign members of the Congress, and these are indeed so numerous that it is often heard to be styled the German Congress in London.

Certain hospitals are enumerated for inspection on each day, so that all cases of interest may be explained by the members of the staffs who are then in attendance to welcome at the respective medical institutions all comers who make their visits in accordance with the daily programme.

The Lord Mayor of London, on Thursday night, entertained some two hundred members of the Congress, including Sir James Paget (President of the Congress), Professor Langenbeck, Sir J. Risdon Bennett, Professor Esmarch, Mr. Prescott Hewett, Professor Charcot, Dr. Pantaleoni, Professor Warlomont, Professor Donders, Professor Virchow, Mr. W. Bowman, Professor Paget, Dr. Billings, Dr. Acland, Dr. Pasteur, Dr. Austin Flint, Sir Henry Thompson, Professor Huxley, and Dr. Carpenter. In proposing the loyal toasts the Lord Mayor said that, although he was favored with the presence of a large number of distinguished visitors from various parts of the world, he ventured to think that there was not one but would join heartily in drinking the health of her Majesty, who had set a bright example in every relation of domestic and public life.

The Lord Mayor next gave the toast of the evening, "Success to the International Medical Congress," stating the pleasure it gave him to extend the hospitality of the Mansion House to men so distinguished. This was an age of congresses. There were congresses upon all subjects; but although he had had other gatherings of the kind, and hoped to welcome more, yet he believed that no meeting had ever taken place there or in London more important than this one. It was impossible to estimate what the interchange of thought and what the result of the expression of opinion of these distinguished men might effect in relation to medical science. The diffusion of knowledge, the alleviation of human suffering, and the happiness of mankind he could not doubt would be the result of this Congress. Seldom had the City witnessed such an assemblage. There were present men distinguished for keen scientific research and high intellectual power—men who had made their names famous, not only in their profession but by their works.

Sir James Paget (President of the Congress), who was received with loud cheers, said: "I have the honor to return thanks this evening, not for myself alone, although I feel very profoundly, and from my heart thank the Lord Mayor for the very kind terms in which he has spoken of myself, but I have to return thanks also for nearly all present. It seems to me well that we who have met to settle questions upon which we differ should have things brought before us on which we can be completely unanimous, and one of those is that we can all agree to return our very best thanks to the Lord Mayor for the hospitality—the brilliant hospitality—with which he has received us to-night. We are among those who in the investigation of science have to look for constant change, and yet none more than ourselves admire the traditions which represent definite popular feeling. And, in this country, no institution can do this more perfectly than that of the Lord Mayor and Corporation of London. I believe that, had we been asked what honors we should like best to receive, we should have replied that it would be first of all that which we have had—the patronage of her Majesty the Queen, then that of the presence of the Prince of Wales at our first meeting, which also we have had, and next that of the approval of the Lord

Mayor and the Corporation of London, who represented the magnificent hospitality attached to the merchant princes of London—they represent by longest tradition the value of popular election—for their election is still absolutely and completely popular—they represent those who in this country are prominent for their loyalty, that is law-loving, and who are allowed by law still to exist, and are allowed also to have the great privilege of self-government, a privilege which is still complete in the Lord Mayor and Corporation. Of the many Lord Mayors I have known, there is not one who more thoroughly, by his long life of personal devotion to his fellow-citizens, deserves this honor than his lordship. We boast that we are very hard workers for science, but not one works harder or more heartily for the benefit of his fellow-men than the Lord Mayor. Every day is occupied in giving and receiving hospitality, and that not for personal or private ends, but for the welfare of the people amongst whom he lives. I must not forget that to-night we have to return thanks to the whole Corporation for the invitations that they have given us to a *conversazione* at the Guildhall to-morrow evening. The hospitality at the Mansion House is boundless and of almost daily occurrence, but at the Guildhall it is of necessity rare. There, however, we shall have the opportunity of seeing something above and beyond hospitality—there we shall see a fine collection of relics of ancient London, some of the very best examples of Roman remains; and there, too, we shall find the rarest records of the history of England, and have the privilege of seeing a library rich in excellent works admirably arranged, and open upon terms of the most absolute liberality. In returning thanks, I have to reply quite as much for the honors which are in prospect as for those which we have just enjoyed."

The Lord Mayor proposed "Our Foreign Guests," to which Professor von Langenbeck, Professor Trellat, Dr. Pantaleoni, and Dr. Austin Flint responded. Professor Donders gave "The Health of the Lord Mayor," who proposed in reply, "The Aldermen and Corporation," coupling with the toast the name of Mr. Alderman Stone. Mr. Alderman and Sheriff Fowler, M. P., responded for the health of the sheriffs, and the Lord Mayor for that of the Lady Mayoress, proposed by Sir J. R. Bennett.

One of the few drawbacks to the vast attraction which this session has furnished, was to be found in the small proportion of its members which could be invited to the Lord Mayor's banquet, but this grievance has been minimized by the magnificent *conversazione*, at the Guildhall, which the Corporation of London provided, at an expense of two thousand pounds sterling, in honor of the Congress, at whose disposal no less than two thousand five hundred tickets were placed. This Guildhall *conversazione* proved an even more stupendous success than that at South Kensington, and last night the guests of the Corporation found that interesting old Guildhall most completely adapted for their accommodation and entertainment. The arrangements, which were on a grandly comprehensive scale, displayed the resources of the library and museum, which were extensively supplemented by private aid, and by loans of plate from the various civic guilds. In the temporary ante-chamber, the guests were received by the chief magistrate and the lady who so gracefully takes part in dispensing the hospitalities of the present mayoralty. All, or nearly all, those distinguished physicians and surgeons who have taken part hitherto in the doings of

the Congress were present; and, as a great many of the foreign members are accompanied to England by their wives or daughters, the Guildhall and the many chambers pertaining thereto were filled by an animated assemblage, one-half of which was feminine. At the height of this cheerful reunion, the many tongues that were heard together sufficiently justified the term "International." French, German, Spanish, Dutch, Italian, Scandinavian, and English were all at once audible; and it was evident that taciturnity had been expelled from a gathering which found everywhere something fresh to talk about. There was, moreover, need of speaking in a louder tone than usual; for the hum around the talkers was like a strong flood of sound, overpowering single currents and eddies. In the Guildhall itself, the Coldstream Guards band played the music of nearly as many countries as were represented in the crowd of visitors. The same thing was done by the Royal Artillery band, while in the Council Chamber a vocal and instrumental concert was given by the students of the Guildhall School of Music.

Among the objects exhibited in the library, besides the ancient charters, books, antiquities, maps, manuscripts, autographs, and curious and early-printed books, were the city jeweled sceptre, tendered to sovereigns on the occasion of royal visits, and the city purse. The former of these historical symbols displays a curious mixture of dates, having been repaired, altered, and remodeled at widely different periods. Most ancient of the portions thus brought together by time are the crystals and an alloy of gold which has not been used in art manufacture since the Conquest. As for the purse, which typifies the city's wealth, it is of gold and silver embroidery, less venerable, but still as old as the first of the Tudor kings. In the Museum were exhibited a collection of Roman, Romano-British, Saxon, and mediæval objects of all descriptions found in the city of London. In the reading-room next the library a selection of the Corporation plate, chronologically arranged, and lent by the Lord Mayor, was accompanied by similar loans from the Armorers' and Braziers', the Barber-Surgeons', the Sadlers', the Skinners', the Clothworkers', the Distillers', the Goldsmiths', the Fishmongers', the Haberdashers', the Merchant Tailors', the Leather Sellers', the Stationers', and seventeen or eighteen other companies. In the Guildhall, interspersed with palms, ferns, and flowers, which everywhere made a pleasantly varied show, sculptures and choice specimens of Doulton ware found places in which they appeared to advantage. The electric lighting was everywhere effective; but the chief because the newest attraction in this general system of illumination was afforded by the storage of electricity, this being the method employed to light the committee-room and the staircase. Crystal drops, containing each a brilliant and at the same time soft and mellow light, resembling in quality the flame of a wax candle, but much more powerful than a single light of this nature would be, had been charged at the West End of London, and taken to the Guildhall, where they hung magically on the circular rim of a chandelier. This light has the peculiar charm so much desired by wearers of diamonds and other precious stones, causing, as it does, those ornaments to flash from all their facets rays of prismatic splendor. Refreshments were served in the Exchequer Court, the South Court, and the Crypt, a plan being furnished with every handbook, enabling the guests to circulate throughout all the

mazes of the building, and to find those places without difficulty. In short, all the arrangements were admirable; and if any anxiety had been felt, in expectation of undue pressure, it was relieved by the smoothness with which the whole entertainment went, from first to last.

One hears on all sides of the satisfaction which the members attending the various sections feel at the character of the work which is daily done therein, but the vast extent of which defies useful commentary until the volume of Transactions shall appear.

The practice of exhibiting, at stated times, groups of living specimens illustrative of rare forms of disease proves most valuable.

The members of the London School of Medicine for Women, who have been debarred participation in the work of the International Medical Congress, have manifested a graceful magnanimity in their resolution not to hold aloof from the hospitalities of this important gathering. Their house in Henrietta Street, Brunswick Square, rejoices in a large, old-fashioned — and therefore highly fashionable — garden; and yesterday this oasis in the desert of the west-central district was beautified with tasteful devices of flags and festoons, as also with a profusion of flowers from all parts of the country. From five till seven o'clock a company, including many distinguished people, enjoyed the pleasures provided for their entertainment; and the beauty of the weather, tempered in its heat by a delicious breeze, completed the success of this elegant reception. Among those who were present may be named the Dowager Countess of Buchan, the Right Hon. Henry Fawcett, M. P., and Mrs. Fawcett, Professor Ray Lankester, Sir Arthur and Lady Hobhouse, Dr. Carpenter, Professor Landolt, Professor Busch, Dr. Elizabeth Blackwell, Mrs. Garrett Anderson, M. D. Miss Ker, M. D. Miss MacLaren, M. D. Mrs. Westlake, Dr. A. C. Hépites, Professor MacAlister, Professor Struthers, Dr. Fanvel, Dr. G. De Mussy, Mr. Luther Holden, Professor Binz, Mrs. Foggo, Dr. Annie Barker, and Mrs. Thorne, the honorary secretary of the institution. A band played a miscellaneous selection of music, Handel's triumphal march, "See, the conquering hero comes," being introduced as Miss Prideaux, Mrs. Scharlieb, and Miss Tomlinson, who, on Thursday, passed first M. B., in the London University examination, entered together. The foreign guests, some of whom visited the adjacent Royal Free Hospital, with which the school is in association, were unanimous in their expression of the pleasure which this garden party afforded them.

Dr. Billings' address, which was looked forward to with the highest anticipations, was listened to yesterday afternoon by a vast and distinguished audience, who were at once interested, instructed, and delighted. At its close the president of the Congress thanked Dr. Billings in a brief but eloquent and beautiful speech, which was of additional interest as recording some incidents in the early professional struggle of the justly exalted and greatly beloved speaker. To-morrow, Sunday, a large party will be the guests of Sir Trevor Lawrence at his picturesque country seat. Special services will be held in the cathedrals here, and arrangements have been made for those who wish to visit Kew Gardens, which offer natural beauties scarcely second to those afforded by old Druid Hill Park, Baltimore, but very inadequately appreciated by the vast majority of Londoners proper.

This Congress will close on Tuesday, that is to say, on the very day of the formal opening of the annual meeting of the British Medical Association, which will this year be held in the beautiful Isle of Wight, where, from the unusual attraction afforded by the recent discovery of a buried Roman villa in good preservation, there will be a second reunion of very many who are this week too busy in London to fully avail themselves of the opportunity for personal intercourse which hosts and guests covet alike.

LETTER FROM PORTLAND.

MEDICAL MATTERS IN MAINE. — MEDICAL LEGISLATION. — AN ANATOMICAL BILL. — THE STATE LUNATIC ASYLUM. — A CHARTER FOR AN ECLECTIC MEDICAL COLLEGE. — THE TWENTY-NINTH ANNUAL MEETING OF THE MAINE MEDICAL ASSOCIATION. — THE MEDICAL SCHOOL OF MAINE.

MR. EDITOR, — In reviewing the course of medical events in Maine during the past twelvemonth, we find several items of more than ordinary interest. Foremost among them is the action of the legislature with reference to an anatomical bill. As the readers of the JOURNAL are doubtless aware, it has been practically impossible to obtain dissecting material in this State in any lawful way. Every subject has been secured by some clandestine process, and every year new difficulties have arisen in the path of the student or practitioner who desired to acquire or revive his knowledge of human structure. For many years the Maine Medical Association has occasionally made systematic efforts to induce our lawmakers to pass a bill which should do even scant justice to the profession, but in vain. There has never been any considerable difficulty in convincing a majority of the legislators of the necessity of dissection and the propriety of such a law as was prayed for, but the trouble lay in persuading them to run the risk of incurring the displeasure of their constituents, as they were very certain to do if they voted for any such enactment. It has often been said, and apparently with truth, that no advocate of an anatomical bill was ever again allowed to represent his town at the capitol; indeed, the odium which has attended the defense of such a measure has sometimes amounted to complete social and political ostracism, and has fairly driven men from the State. Nothing daunted, however, this Association returned to the struggle this year, under the leadership of its president, Dr. Greene, of this city, and by pursuing a sagacious and methodical plan of attack, succeeded in securing the passage of a bill, which, although imperfect and weighted with difficult conditions, is a gain over its predecessor. The device employed was to have every senator and representative approached before the meeting of the legislature, and, if possible, pledged to support the measure, so that, it was hoped, when the bill was presented, it would go through the several steps to its final passage without discussion. But, as almost always happens, some irrepressibles wanted to display their eloquence and the jealousy with which they guarded the interests and feelings of the dear people, and a hot discussion was at once precipitated upon the commons of the commonwealth. Objections were raised and amendments offered, and for a time it looked as if everything was lost; but the bill, greatly mod-

fied and weakened, was squeezed through, and, after long and anxious delay, received the signature of the governor. This "act for the promotion of medical science" is in substance as follows: —

Section first provides a punishment of not more than five years' imprisonment or fine not exceeding three thousand dollars for the having in possession, for anatomical purposes, any part of the body of a person dying in Maine, unless obtained under this act or a certain previous statute which never has furnished and never will furnish a subject.

According to section second, any inhabitant of Maine who wants to be dissected when he is dead may be accommodated, if no relative or family connection objects; that is to say, if his second-cousin's wife, whom he would not knowingly have gratified in his lifetime, chooses out of spite to protest against the dissection, the law utterly disregards the last testament of a departed citizen as far as it relates to the disposal of his body, the one thing before all others which he while living considered, in common with everybody else, was most peculiarly his own.

The third section provides that unclaimed bodies shall be subject to the use of the Medical School of Maine, which may deliver its surplus cadavera to any regular physician for anatomical purposes in this State.

In the fourth section are prescribed rules for notifying the school of the existence of bodies and for their delivery to the proper persons, and requires a hundred dollars bond that each carcass shall be decently buried after it has fulfilled its scientific mission. Thirty dollars fine is to be paid for the violation of the provisions of this section.

In order to satisfy the squeamishness of certain legislators, an act additional was passed immediately afterwards, providing that every dead body shall be embalmed as soon as it is received at the school, and there kept intact for thirty days; and also that an identifying description be kept in a special book. Any of the corpse's family may claim and remove it at any time within the month.

It will be seen that the new law does not make it exactly an easy proceeding to secure a subject for dissection. Whether or not any can be obtained is a serious question which is as yet unsolved. No attempt to test its workings is to be made until the warm months are gone, and we must wait until autumn for developments. One would think that the original act was sufficiently stringent; it is feared that the additional statute is so exacting as to be a complete paralyzer.

Another piece of legislative work in which the medical profession, as well as the community generally, took a good deal of interest, was the investigation of the Maine Insane Hospital. For some time rumors had been circulated to the effect that serious abuses were allowed in the institution, and the trustees requested an official investigation. A committee of the legislature held sessions on twenty different occasions, inviting testimony from all concerned; a few direct and specific charges of mismanagement were made and patiently investigated, and the committee presented three reports. That of the majority is an eager and fulsome exculpation of the officers, and represents the hospital to "be fully up to the highest standard of efficiency in all its departments." One of the minority reports agrees in most points with that of the majority, but recommends that all additions to the hospital shall be on the cottage plan, and that a female physician be employed. The

second minority report, presented by a homœopathic physician, represents that abuses have occurred, and makes various suggestions, some of them very sensible, looking to the improvement of the management. Naturally there are diverse opinions in the profession about the matters involved in the controversy; but probably the large majority of physicians who have taken the pains to look into them would agree substantially that it is unfortunate that party politics should influence the appointment and tenure of the trustees, as at present; that these officers ought to be selected solely with reference to their peculiar fitness for the position; that four hundred and fifty insane people are too many to be treated with the best results in one institution; that, if this number is to be congregated in one place, more than three physicians are required to minister to their medical wants; and that there is room for very decided improvement in the present superintendency. This last point, as is well known, has been discussed for years in the board of trustees and in the governor's council, with a very general agreement of opinion. Nobody considers the superintendent a bad, dishonest, inactive, or cruel man; his personal character has never been assailed; but he has reached an age when a certain rigidity of mental structure renders most men incapable of adopting new methods, and, in addition, has a physical infirmity which must seriously diminish his capacity for usefulness in this position. There is need of new blood in the place, and unless a change is made before long it will take more than the ungutted of a flattering legislative report to soothe the dissatisfaction which is constantly growing among those who have occasion to be especially interested in the institution. It is not believed that the hospital is in particularly bad condition; but it would be a matter of humanity and of State pride to have it in a conspicuously good one. There is no reason why the most approved methods of treatment should not be pursued here as well as elsewhere; it is quite as possible for Maine to make valuable contributions to the scientific study of insanity as for most other States; but we look in vain to Augusta for light on the subject.

This year's legislature was applied to for a charter for an eclectic medical college to be located in Lewiston. As originally framed, the bill was so worded that, if it had become a law, we should probably have had a diploma-mill in this State whose operations might have rivaled those of the notorious Philadelphia establishments. But fortunately there were a few medical men in the legislature who presented the case so luminously to their fellows that essential alterations were made in the proposed charter, and the amount of damage of which the concern will be capable is greatly diminished. As now constituted, the law requires of every would-be eclectic M. D. the successful passage of as severe a public examination in the fundamental branches of medicine as the candidates in the Medical School of Maine are subjected to before they are allowed to graduate.

As it is improbable that members of the regular profession will attend the examinations, the faculty and friends of the institution will have everything all their own way, and the amount of protection which society will experience is likely to be rather small. But it has more appearance of decency, at all events, to have proper regulations, even if they are never obeyed; and, in case of especially flagrant abuse, there is something definite to work from.

The Maine Medical Association held its twenty-ninth annual session in this city in June. The president's address was a very timely denunciation of private preceptorship, and it is devoutly to be hoped that every member of the profession will take its lesson to heart. There would then quickly be a selecting-out of the poorly qualified students, and those who were able to stand the tests would be obliged to abandon their desultory ways and betake themselves to earnest, systematic work. But he who looks for a sudden and radical change is doomed to a bitter disappointment. The discussion is not new, even in this Association. Nine years ago Professor C. F. Brackett devoted the annual oration to the subject of methods in medical education, and took precisely the same ground; but, although the argument was thoroughly convincing and unanswerable, and was presented in a delightfully trenchant style, there has been no noticeable decrease in the number of private preceptors, no marked increase in the attendance at the school for instruction. The habit of taking students is so firmly fixed, and it is so convenient and gratifying to many men's complacency to have pupils about their offices, that not a few appeals will have to be made before the vicious system is replaced by one which is rational. It is so easy to applaud an eloquent speech which denounces our shortcomings, and also to find an excuse for disregarding its teachings when we have occasion to practice them! Oh, for some first-class man who, in this cause, would be willing to make himself disagreeable to his medical brethren individually, and plead with them concerning their iniquities, even as doth an elder at a camp-meeting; what a revival in medical education there would be, and what an uplifting from the gall of bitterness and the sin of private preceptorship!

On the first day of the Association's meeting, a motion was made to exclude from the reports with which the daily papers were furnished all mention of cases and medical papers, on the ground that it was inconsistent for the society to do for any member what it would regard as unseemly if done by the member for himself; but the movement received almost no support, and did not prevail. When next charges are preferred against some member for violating the code by inserting accounts of his skill in the non-medical press, the censors will have a delicate task to steer between the rocks of the ethics and the gulf of the Association's liberality without wrecking their craft.

A rule was adopted by which all nominations for honorary membership must take the same course as applications for active membership. Hitherto it has been the practice to propose from the floor without warning, so that a nomination was practically equivalent to an election; for to rise and publicly oppose a man's admission is an ungracious task which no one covets and few have the moral hardihood to perform. The result has been an altogether too lavish distribution of the society's favors; but, in future, they will be bestowed with more discrimination, and will, consequently, be of greater value.

The reports of cases and papers were of ordinary interest, and excited considerable discussion. Dr. A. K. P. Meserve, of Buxton, York County, was chosen president, and the other officers were in the main re-elected. An entire evening was spent in a social way, an excellent banquet being provided at the expense of the society, and many ladies accompanying the mem-

bers. This entertainment was favorably commented on, but as no arrangement was made for its repetition next year the ill-natured are afforded a chance to suppose that there was a bee in even that honey.

In one respect the meeting was the most enjoyable for years. The discussion of individual grievances, which has often wasted the time and disgusted those who prefer to have the censors settle quarrels outside the public meetings, was conspicuous by its absence; and it is quite certain that any attempt to revive the former troublesome method would have been promptly crushed by the united opposition of a large number of the most influential men in the society.

The delegates to the Medical School of Maine reported it to be in an extraordinarily flourishing condition, the number of students exceeding that in any preceding year, and their quality being a noticeable improvement on that of former classes. In every respect the School maintains its fair reputation. The report on the Portland School for Medical Instruction was also highly commendatory.

PORTLAND, August 10, 1881.

HAPPY DOCTORS.

OFFICIAL PROGRAMME OF THE INTERNATIONAL MEDICAL CONGRESS.

First day. Grand banquet. Interesting experiments with various wines. Confidential exchange of experience after the third bottle.

Second day. Grand *déjeuner*. Surgical operations on cold fowls and raised pies. General investigation of "mixing." Valuable results obtained by taking a combination of champagne, sherry, port, claret, pale ale, and chartreuse vert.

Third day. Garden party. Examination of the action of the muscles in the game of lawn tennis. Close study of strawberries and cream and champagne cup. Supper experiment at the Albion. Extempore lecture upon the benefits to be derived by taking whisky and water internally before retiring to bed.

Fourth day. Select dinner party of savants interested in food. Careful consideration of the effect upon the system of turtle soup, curried whitebait, canvas-back ducks, and an entirely new and original with-you-please pick-me-up made of sardines, olives, truffles, cayenne pepper, tomatoes, capers, herring roes, fowls' livers, and tarragon vinegar. Human capacity for absorbing champagne in extra large doses practically tested. After the experiments a long consultation with the police.

Fifth day. Psychological picnic. Exercise of the nerve power of the lower limbs to the sounds of a military band. Interesting operation of a quadrille, a polka, and a waltz. Day finished with a scientific supper. Preparations of different kinds of meat. Practical lectures upon the anatomy of the fowl, the duck, and turkey. Experiments in wine temperature. Claret seventy and champagne four degrees below zero. Perambulating difficulties and optical delusions. Exercise of the vocal chords. Subject: "We won't go home till morning."

Sixth and last day. All the foreign doctors ill in bed, sending for all the English doctors. General prescription: Large doses of soda water! — *From Punch.*

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 19, 1881, TO AUGUST 26, 1881.

McKEE, J. C., major and surgeon. By direction of the Secretary of War the leave of absence on surgeon's certificate of disability granted in S. O. No. 177, August 19, 1880, is extended three months. Par. 3, S. O. 189, A. G. O., August 18, 1881.

WEBSTER, WARREN, major and surgeon. Granted leave of absence for twenty (20) days. S. O. 149, Dept. of the East, August 24, 1881.

McCLELLAN, ELY, major and surgeon. Relieved from duty in the Department of the Columbia, and to proceed to Louisville, Ky., and report by letter, upon his arrival there, to the Surgeon General. S. O. 193, A. G. O., August 23, 1881.

WOODHULL, A. A., major and surgeon. Relieved from duty in the Department of California, and to proceed to New York city, and report by letter, upon his arrival there, to the Surgeon General. S. O. 193, A. G. O., August 23, 1881.

BROWN, HARVEY E., major and surgeon. Relieved from duty in the Department of Texas, and to proceed to New York city, and report by letter, upon his arrival there, to the Surgeon General. S. O. 192, A. G. O., August 22, 1881.

HUBBARD, VAN BUREN, major and surgeon. The leave of absence granted him in S. O. 169, A. G. O., August 26, 1881, is extended eight months with permission to go beyond sea. S. O. 193, A. G. O., August 23, 1881.

DICKSON, J. M., captain and asst. surgeon. Relieved from duty in the Department of the Columbia, and to proceed to New York city, and report by letter, upon arrival there, to the Surgeon General. S. O. 193, A. G. O., August 23, 1881.

COWDREY, S. G., captain and asst. surgeon. Relieved from duty in the Department of the Platte, and to proceed to New York city, and report by letter, upon arrival there, to the Surgeon General. S. O. 193, A. G. O., August 23, 1881.

SHANNON, W. C., captain and asst. surgeon. Relieved from duty at Fort D. A. Russell, Wyo., and assigned to duty as post surgeon at Fort Thornburgh (junction of White and Green rivers), Utah. S. O. 81, Department of the Platte, August 22, 1881.

GARDNER, E. F., asst. surgeon. Upon being relieved by asst. surgeon Bushnell, is relieved from duty in Department of Dakota, and will comply with Par. 3, S. O. 171, A. G. O. S. O. 150, Department of Dakota, August 17, 1881.

ROBINSON, SAM'L Q., 1st lieutenant and asst. surgeon. Relieved from duty in the Department of Dakota, and to proceed to Boston, Mass., and report by letter, upon arrival there, to the Surgeon General. S. O. 193, A. G. O., August 23, 1881.

POWELL, J. L., 1st lieutenant and asst. surgeon. Granted leave of absence for one month, to take effect as soon as the medical director of the department shall have completed certain inspection duty at Fort Stockton, Texas. S. O. 99, Department of Texas, August 13, 1881.

BUSHNELL, G. E., asst. surgeon. Relieved from temporary duty at Fort A. Lincoln, D. T., to take effect on his arrival at that post, and to proceed to Fort Ellis, M. T., and report to the commanding officer for duty at that post, to relieve asst. surgeon E. F. Gardner. S. O. 150, Department of Dakota, August 17, 1881.

The tenth semi-annual meeting of the New Hampshire Medical Society will be held at "The Wentworth," Newcastle, N. H., on Tuesday, September 6, 1881.

BOOKS AND PAMPHLETS RECEIVED. — A Paper on the Relations of the Minute Blood-Vessels to the Fat Cells in the Fascia of the Cat's Neck, illustrated by Photographs and Drawings, read before the Richmond Microscopical Society. By Wm. R. Weisinger, M. D., of Manchester, Va. Richmond, Va. Johns & Goosley. 1881.

Post-Partum Atrophy of the Uterus. By Walter Coles, M. D. St. Louis. (Reprint.)

A Treatise on Comparative Embryology. By Francis M. Balfour, LL. D., F. R. S. In two Vols. Vol. II. London. MacMillan & Co. 1881.

A System of Surgery, Theoretical and Practical, in Treatises by various Authors. Edited by T. Holmes, M. A. Cantab. Surgeon and Lecturer on Surgery at St. George's Hospital. First American from Second English Edition. Thoroughly Revised and much Enlarged by John N. Packard, M. D. Assisted by a large corps of the most eminent American Surgeons. In three Volumes, with many Illustrations. Vol. I. Philadelphia. Henry C. Lea's Son & Co. 1881. (A. Williams & Co.)

INTERNATIONAL MEDICAL CONGRESS,
LONDON, 1881.

AN ADDRESS ON OUR MEDICAL LITERATURE.

BY JOHN S. BILLINGS, M. D.,
Surgeon United States Army.

WHEN I was surprised by the honor of an invitation to address this Congress, my first thought was that it must be declined, for the simple but sufficient reason that I had nothing to say that would be worth occupying the time of such an assemblage as it was evident this would be. But while thinking over the matter, and looking absent-mindedly at a shelf of catalogues and a pile of new books and journals awaiting examination, it occurred to me that, perhaps, some facts connected with our medical literature, past and present, from the point of view of the reader, librarian, and bibliographer, rather than from that of the writer or practitioner, might be of sufficient interest to you to warrant an attempt to present them, and—the wish being probably father to the thought—I decided to make the trial.

When I say “our medical literature,” it is not with reference to that of any particular country or nation, but to that which is the common property of the educated physicians of the world as represented here to-day—the literature which forms the intranational and international bond of the medical profession of all civilized countries, and by virtue of which we, who have come hither from the far west and the farther east, do not now meet, for the first time, as strangers, but as friends, having common interests, and, though of many nations, a common language, and whose thoughts are perhaps better known to each other than to some of our nearest neighbors.

It is usual to estimate that about one thirtieth part of the whole mass of the world's literature belongs to medicine and its allied sciences. This corresponds very well to the results obtained from an examination of bibliographies and catalogues of the principal medical libraries. It appears from this that our medical literature now forms a little over 120,000 volumes properly so called, and about twice that number of pamphlets, and that this accumulation is now increasing at the rate of about 1500 volumes and 2500 pamphlets yearly.

There are at the present time scattered over the earth about 180,000 medical men, who, by a liberal construction of the phrase, may be said to be educated; that is, who have some kind of a diploma, and for whose edification this current medical literature is produced. Of this number about 11,600 are producers of, or contributors to, this literature, being divided as follows: United States, 2800; France and her Colonies, 2600; the German Empire and Austro-Hungary, 2300; Great Britain and her Colonies, 2000; Italy, 600; Spain, 300; all others, 1000. These figures should be considered in connection with the number of physicians in each country; but this I can only give approximately as follows: United States 65,000; Great Britain and her Colonies, 35,000; Germany and Austro-Hungary, 32,000; France and her Colonies, 26,000; Italy, 10,000; Spain, 5000; all others, 17,000.

It will be seen from these figures that the number of physicians who are writers is proportionately greatest in France and least in the United States. As regards France, this is largely due to the requirement of

a printed thesis for graduation, which of itself adds between six and seven hundred annually to the number of writers.

The special characteristics of the literature of the present day are largely due to journals and transactions, and this is particularly true in medicine. Our periodicals contain the most recent observations, the most original matter, and are the truest representations of the living thought of the day, and of the tastes and wants of the great mass of the medical profession, a large part of whom, in fact, read very little else. They form about one half of the current medical literature, and in the year 1879 amounted to 655 volumes, of which the United States produced 156; Germany, 129; France, 122; Great Britain, 54; Italy, 65; and Spain, 24. This is exclusive of journals of pharmacy, dentistry, etc., and of journals devoted to medical sects and isms.

[Tables were here appended, showing by nations the number of works and journal articles upon the practice of medicine, surgery, obstetrics, hygiene, etc., for the years 1879 and 1880. A marked increase has occurred in the literature of hygiene during the last two years, and this especially in England, France, Germany, and the United States. The literature of diseases of the nervous system, of ophthalmology, otology, dermatology, and gynecology is also increasing more rapidly than that of the more general branches.]

These figures represent merely the opinions of an individual—first as to whether each treatise or pamphlet included in these statistics was worth noting, and second, as to how it should be classed. Had everything been indexed the figures, for journal articles at least, might have been nearly doubled; while, if the selection had been made by a more severe critic, they might have been reduced one half.

Be that as it may, I think we can take them as indicating certain differences in the direction of work of the medical authors of the great civilized nations of the earth; but they must be considered as approximations only; and the statistical axiom must be remembered, that the results obtained from a large number of facts are applicable to an aggregate of similar facts but not to single cases. There will be a certain number of medical books and papers printed next year, just as there will be a certain number of children born; and as we can within certain limits predict the number of these births and the proportion of the sexes, or even of monsters, so we can within certain limits predict the amount and character of the literature that is yet to come, the ideas that are yet unborn. The differences are due to race, political organization, and density of population. As Dr. Chadwick has pointed out, in speaking of the statistics of obstetric literature, one of the chief causes of the multiplication of medical societies is geographical. “In England it is possible for those who are specially interested in gynecology and obstetrics to attend the meetings of the Obstetrical Society of London, whereas in America the distances are so great that this is impossible.” Speaking broadly, we may say that at present Germany leads in scientific medicine both in quantity and in quality of product, and that the rising generation of physicians are learning German physiology. But the seed has gone abroad, and scientific work is receiving more and more appreciation everywhere.

Seven years ago, Professor Huxley declared that, if a student in his own branch showed power and origi-

nality, he dared not advise him to adopt a scientific career, for he could not give him the assurance that any amount of proficiency in the biological sciences would be convertible into the most modest bread and cheese. To-day I think he might be bolder, for such a fear would hardly be justifiable — at all events in America. — where such a man as is referred to could almost certainly find a place, bearing in mind the professor's remark that it is no impediment to an original investigator to have to devote a moderate portion of his time to giving instruction either in the laboratory or in the lecture-room.

I have said that, as regards scientific medicine, we are at present going to school to Germany. This, however, is not the case with regard to therapeutics, either external or internal, in regard to which I presume that the physicians of each nation are satisfied as to their own preëminence. At all events it is true that, for the treatment of the common diseases, a physician can obtain his most valuable instruction in his own country, among those whom he is to treat. Just as each individual is in some respects peculiar and unique, so that even the arrangement of the minute ridges and furrows at the end of his forefinger differs from that of all other forefingers, and is sufficient to identify him; and as the members of certain families require special care to guard against hæmorrhage, or insanity, or phthisis, so it is with nations and races. The experienced military surgeon knows this well; and in the United States, which is now the great mixing ground, illustrations of race-peculiarities are familiar to every practitioner.

The separation of biological study from practical medicine, which has of late years become quite marked in the literature of the subject, has its advantages and disadvantages. Thus far the former have far outweighed the latter, and both the science and the art of medicine have been promoted thereby. But are not the physiologists, or, as I believe they prefer to be called, the biologists, separating themselves too completely from medicine for the best interests of their own science, in that they are neglecting human pathology? In our hospital wards and among our patients nature is continually performing experiments which the most dexterous operator cannot copy in the laboratory, — she is, as Dr. Michael Foster says, "a relentless and untrammelled vivisector, and there is no secret of the living frame which she has not, or will not, at some time or place, lay bare in misery and pain."

Now while it is true that Dr. Foster, in his address before the British Medical Association last year (which address is the clearest exposition of the aims of the physiology of the present day that I have seen), insists upon the fact that all distinctions between physiology and pathology are fictitious, and declares that attempts to divide them are like attempts to divide meteorology into a science of good and a science of bad weather, his conclusion that the pathologist should be trained in methods of physiological investigation seems to me to be only a part of the truth. The tacit assumption is that all, or at least the most important, phenomena of human disease may be reproduced in the physiological laboratory. If this were only true, what a tremendous stride would have been taken towards making medicine a science. Unfortunately it is not so. Many of the most interesting of these phenomena — the most interesting because as yet the most unexplainable — can only be observed in the sick man himself. Nor have

the physiologists as yet made much use of that field which ought to be specially inviting to them — namely, comparative pathology; although the literature of the present time already indicates that a change has begun in this respect.

While it is true that to the graduate of thirty years ago much of the physiological literature of the present day is in an unknown tongue, it is also true that the physiologist of the present, who confines himself to laboratory work, will find himself distanced by the man who keeps his clinical and pathological studies and his experimental work well abreast.

The increase in both the amount and value of the literature of the several specialties in medicine is readily seen by a comparison of recent catalogues and bibliographies with those of twenty or thirty years ago, and this increase still continues at a greater rate than prevails in the more general branches. There are great differences of opinion as to the relative value of this increase, and as to its future effect upon the profession; but there can be no doubt as to the fact. There must be specialties and specialists in medicine, and the results will be both good and evil; but the evils fall largely upon those specialists who have an insufficient general education, — who attempt to construct the pyramid, their knowledge, with the small end as a foundation. It has been said by Dr. Hodgen that "in medicine a specialist should be a skilled physician and something more, but that he is often something else — and something less." There is truth in this; truth which the young man will do well to consider with care before he begins to specialize his studies; but, on the other hand, it is also true that the great majority of men must limit their field of work very much and very clearly if they hope to achieve success. The tool must have an edge if it is to cut. It is by the labor of specialists that many of the new channels for thought and research have been opened; and if the flood has sometimes seemed to spread too far, and to lose itself in shallow and sandy places, it has nevertheless tended to fertilize them in the end.

My experience would show that these statements do not apply to medical books. The folios and quartos of three and four hundred years ago seem to have had great capacity for resistance to ordinary destructive forces. Perhaps much of this is due to the fact that they are not usually injured by too much handling or perusal. True, they are gradually becoming rarer; but, at the same time, by means of properly organized libraries, they are becoming more accessible to all who wish to really use them, and not merely to collect and hide them away. They drift about like the sea-weed, but the survivors are gradually finding secure and permanent resting places in the score of great collections of such literature which the world now possesses. At present, the currents of trade are carrying them in relatively large numbers to the United States, where medical collectors and specialists are among the best customers of the antiquarian booksellers of Europe. I could name a dozen American physicians who have given to European agents almost unlimited orders for books relating to their several specialties, and upon their shelves may be found books of the 15th and 16th centuries, which may be properly marked as "rarissimi."

Not that the rarest books are by any means the oldest. The collector who seeks to ornament his shelves with the *Rose* of John of Gaddesden, or the *Lily* of Bernard de Gordon, the first folios of Avicenna or of

Celsus, or almost any of the eight hundred medical incunabula described by Hain, will probably succeed in his quest quite as soon as the one who has set his heart on the first editions of Harvey or Jenner, the American tracts on inoculation for small-pox, or complete files of many of the journals and Transactions of the present century.

Whatever may be the chosen line of the book-collector, he is the special helper of the public library, and this whether he intend it or not. In most cases his treasures pass through the auction-room, and sooner or later the librarian, who can afford to wait, will secure them from further travel. Thanks to the labors of such collectors, I think it is safe to say, — what certainly would not have been true twenty years ago, — that if the entire medical literature of the world, with the exception of that which is collected in the United States, were to be now destroyed, nearly all of it that is valuable could be reproduced without difficulty.

What is to be the result of this steadily increasing production of books? What will the libraries and catalogues and bibliographies of a thousand, or even of a hundred, years hence be like, if we are thus to go on in the ratio of geometric progression which has governed the press for the last few decades? The mathematical formula which would express this, based on the data of the past century, gives an absurd and impossible conclusion; for it shows that, if we go on as we have been going, there is coming a time when our libraries will become large cities, and when it will require the services of every one in the world, not engaged in writing, to catalogue and care for the annual product. The truth is, however, that the ratio has changed, and that the rate of increase is becoming smaller. In western Europe, which is now the great centre of literary production, it does not seem probable that the number of writers or readers will materially increase in the future; and it is in America, Russia, and southern Asia, that the greatest difference will be found between the present amount of annual literary product and that of a century hence.

The analogies between the mental and physical development of an individual, and of a nation or society, have been often set forth and commented on; but there is one point where the analogy fails as regards the products of mental activity, — and that is, that as yet we have devised no progress for getting rid of the exuvia. Growth and development in the physical world imply the changes of death as well as of life — that with the increase of the living tissues there shall also be the excretion and destruction of dead, outgrown, and useless matters which have had their day and served their purpose. But *litera scripta manet*. There is a vast amount of this effete and worthless material in the literature of medicine, and it is increasing rapidly. Our literature is in fact something like the inheritance of the golden dustman, but with this important difference, namely, that when the children raked a few shells or bits of bone from the dustman's heap, and, after stringing them together and playing with them a little while, threw them back, they did not thereby add to the bulk of the pile; whereas our preparers of compilations and compendiums, big and little, acknowledged or not, are continually increasing the collection, and for the most part with material which has been characterized as "superlatively middling, the quintessential extract of mediocrity." A large medical library is in itself discouraging to many inquirers, and I have become quite

familiar with the peculiar expression of mingled surprise, awe, and despair, which is apt to steal over the face of one not accustomed to such work, when he first finds himself fairly in the presence of a mass of material which he wishes to examine for the purpose of completing his ideal bibliography of — let us say epilepsy, or excision, or the functions of the liver.

Let such inquirers, as well as those who regret that they have no access to large libraries, and must therefore to rely on the common text-books and current periodicals for bibliography, console themselves with the reflection that much the larger part of all of our literature which has any practical value belongs to the present century, and, indeed, will be found in the publications of the last twenty years.

There are a few medical books written prior to 1800 which every well educated man should — I will not say read, but — dip into, such as some of the works of Hippocrates and Galen, of Harvey and Hunter, of Morgagni and Sydenham; but this is to be done to learn their methods and style rather than their facts or theories, and by the great majority of physicians it can be done with more profit in modern translations than in the originals. The really valuable part of the observations of these old masters has long ago become a part of the common stock, and the results are to be found in every text-book.

If, perchance, among the dusty folios there are stray golden grains yet ungleamed, remember that just in front are whole fields waiting the reaper. There is not, and has not been, any lack of men who have the taste and time to search the records of the past; and the man who has opportunities to make experiments or observations for himself wastes his time, to a certain extent, if he try to do bibliographical work so long as he can get it done for him. He wishes to know whether this problem has been attacked before, and with what result — whether there are accounts of any other cases like the one he has in hand. In ninety-nine instances out of a hundred, if the answer to these questions be not given in the current text-books or monographs, it is not worth prolonged search by the original investigator. Yet he should know how to make this search, if only to enable him to direct others; and it is for this reason that a little acquaintance with bibliographical methods of work ought to be obtained by the student.

You will perhaps pardon me for taking as an illustration the Index Catalogue of the Surgeon-General's Office in Washington, as being one with which I am familiar, and which I can venture to comment on without risk of its being thought that I wish to depreciate its value. Taking any given subject in medicine, it is possible for a fairly educated physician to obtain from this catalogue a large proportion of all the references which have any special value, and by so doing to save a vast amount of time and labor. On the other hand, he will find, when he comes to examine the books and articles referred to, that at least one half of them are of no value so long as the other half are accessible, seeing that they are dilutions and dilatations, rehashes and summaries of the really original papers. If the seeker be in the library itself, this does not cause a great waste of time, as he can rapidly examine and lay aside those that do not serve his purpose. But if he be using this catalogue in another library, say here in London, the case is different. It is highly improbable that he will find in any other collection all the books referred to, and then comes the annoyance of

the doubt as to whether he may not be missing some very valuable paper. How is he to know whether or not Smith in his pamphlet on the functions of the pneumogastric has anticipated his own theory of its relations to enlarged tonsils? And in all such cases "*omne ignotum est pro magifico*." In a bibliography of the subject, prepared from the same material as the catalogue, he would either find no mention of Smith's paper, or, better still, a note that his paper is merely an abstract or compilation. The fact that he does not find Smith's book in the London library, nor any allusion to it in the best works on the subject, ought to induce him to ignore it altogether.

In proportion to the energy of the young writer, and his determination to not only note everything that has been written about his subject, but to carry out the golden rule of verifying all his references, he is apt to be led off from his direct research into the many attractive by-paths of quaint and curious speculation which he will find branching off on every side; and this danger must be guarded against, or he will find that he is wasting his time and energy in turning over chaff which has long ago been pretty thoroughly threshed and winnowed.

Do I seem to depreciate the value of the thoughts which our masters have left us, and which have furnished the foundations on which we build? — or to undervalue the importance of the great medical libraries in which are stored these thoughts? — or to speak slightly of the utility of the catalogues and indexes and bibliographies, without which such libraries are trackless and howling wildernesses? If so, I have said what I did not mean to say. The subject has been considered from the point of view of what used to be called the division of labor, but which now I suppose should be called evolution and differentiation; and this has been done because life is short and the art is long — with fair prospects of becoming longer. It is surely unnecessary for me to enter upon any panegyric of books or libraries. As Dr. Holmes says: "It is not necessary to maintain the direct practical utility of all kinds of learning. Our shelves contain many books which only a certain class of medical scholars will be likely to consult. There is a dead medical literature, and there is a live one. The dead is not all ancient, the live is not all modern. There is none, modern or ancient, which, if it has no living value for the student, will not teach him something by its necropsy. But it is with the live literature of his profession that the medical practitioner is first of all concerned."

In medicine, as in social science, we must depend for many facts upon the observation of conditions which occur very rarely, and which cannot be repeated at pleasure. I have already alluded to the importance of nature's vivisections to the physiologist; and a record of a case written a century ago may be just the link that is needed to correlate the results of his experiments of yesterday with existing theories. The case which at first seems unique and inexplicable both receives and furnishes light when compared with ancient records.

A science of medicine, like other sciences, must depend upon the classification of facts, upon the comparison of cases alike in many respects, but differing somewhat either in their phenomena or in the environment. The great obstacle to the development of a science of medicine is the difficulty in ascertaining what cases are sufficiently similar to be comparable; which difficulty, in its turn, largely due to insufficient and erroneous

records of the phenomena observed. This defect in the records is largely due, first, to ignorance on the part of observers; second, to the want of proper means for precisely recording the phenomena; and, third, to the confused and faulty condition of our nomenclature and nosological classifications.

Let us consider each of these points briefly. Very, very few are the men who can, by and for themselves, see and describe the things that are before them. Just as it took thousands of years to produce a man who could see, what now any one can see when shown him, that the star Alpha in Capricorn is really two separate stars, so we had to wait long before the man came who could see the difference between measles and scarlatina, and still longer for the one who could distinguish between typhus and typhoid. Said Plato, "He shall be as a god to me, who can rightly divide and define." Men who have this faculty — the "Blick" of the Germans — we cannot produce directly by any system of education; they come, we know not when or why, "forming a small band, a mere understanding of whose thoughts and works is a test of our highest powers. A single English dramatist and a single English mathematician have probably equaled in scope and excellence of original work in their several fields all the like labors of their countrymen put together."¹

But cannot we do something to increase the number of observers by telling them what to observe? It is probable that much may be accomplished in this direction provided that care be taken to limit the field. Manuals of "what to observe at the bedside and in the post-mortem room" are very well in their way, but can never be made to reach the great majority of the profession, nor would they be of much use if they did. If a few, a very few, distinct specific questions are brought to the attention of a general practitioner, he will often be on the alert for their answer. And it should be remembered that chance may present to the most obscure practitioner an opportunity for observation which the greatest master may never meet.

The great difficulty is to get such questions prepared. They must relate to matters that are just in the nebulous region between the known and unknown — to points not yet clear, but of which we know enough to make it probable that by observing in a definite direction they can be made clear; and to prepare them requires not only knowledge but a certain reaching out beyond knowledge. It usually happens that the man who has this faculty strives to answer his questions himself, and no doubt he can usually do it better than another. But much can be done towards defining and marking out what we do not know, and this has been a powerful aid to the progress of physiology in recent years.

I have had occasion to refer to this in speaking of Dr. Michael Foster's work on physiology, in each section of which an attempt is made to separate that which may be considered as proved from that which is merely probable; and thus almost every page becomes suggestive of work to be done.

Another example of what I mean will be found in a paper on the collection of data at necropsies by Professor H. P. Bowditch of Boston.² Taking the results of an investigation into the absolute and relative size of organs at different periods of life, and in connection

¹ Hes, "Mathematics in Evolution." Popular Science Monthly, 1876, vol. ix, p. 207.

² Trans. Mass. Med. Legal Soc., 1, 1880, p. 139.

with different morbid tendencies, recently published by Professor Beneke, of Warburg, Dr. Bowditch urges the securing as large a number as possible of such data, and selects certain of Professor Beneke's results for special inquiry; for instance, that the "cancerous diathesis is associated with a large and powerful heart, capacious arteries, but a relatively small pulmonary artery, small lungs, well developed bones and muscles, and tolerably abundant adipose tissue." It can hardly be doubted that those who read the papers of Professors Bowditch and Beneke would be induced to examine things which before would have had for them no interest, and therefore to make and record observations in pathological anatomy which otherwise would have been lost.

The second difficulty referred to, namely, the want of means for making accurate records, is one that is yearly growing less. It behooves us to be modest in our predictions as to what may be accomplished in the future towards the solution of our Sphinx's riddle. We see as through a glass darkly, and, except through the glass, in nowise; but at least we have made such progress that what we do see we can to a great extent so record that our successors yet unborn can also see; and it is owing to this fact that a part of the medical literature of the last quarter of the nineteenth century will be more valuable than all that has preceded it.

The word-pictures of disease traced by Hippocrates and Sydenham, or even those of Graves and Tronseau, interesting and valuable as they are, are not comparable with the records upon which the skilled clinical teacher of the present day relies. Yet how imperfect in many cases are even the best of these records as compared with what might be given with the resources which we have at our command. The temperature-chart has done away with the errors which necessarily follow attempts to compare the memory of sensations perceived last week with the sensations of to-day; and the balance and the burette enable us to estimate with some approach to precision the tissue-changes of our patients by the records of change in the excretions which they furnish; but we must still trust to our memory, or to the imperfect descriptions of what others remember, when we attempt to compare the results obtained on successive days by auscultation or percussion, although the phonograph and microphone strongly hint to us the possibility of either accurately reproducing the sounds of yesterday, or of translating them into visible signs, perhaps something like the dot and dash record of the telegraph code, which could then be given to the press, and so compared with each other by readers at the antipodes.

We are beginning to count the blood-corpuscles, and to use photomicrography, but we do not yet apply the latter process to the former so as to enable every reader to count for himself.

The connections of medicine with the physical sciences are yearly becoming closer, and the methods by which the sciences have been brought to their present condition are those by which progress has been, and is to be, made in therapeutics, as well as in diagnosis, or in physiological research. These methods turn mainly upon increasing the delicacy and accuracy of measurements; of expressing manifestations of force in terms of another force, or of dimension in space or time. The balance and the galvanometer, the microscope and the pendulum, the camera, the sphygmograph, and the thermometer, are some of the means by which investi-

gators, at the bedside and in the laboratory, are seeking to obtain records which shall be independent of their own sensations or personal equations; which shall be taken and used as expressing, not opinions, but facts; and with every addition to, or improvement in, these means of measurement and record, the field of observation widens, and new and more reliable materials are furnished for the application of logical and mathematical methods.

Upon the third difficulty which has been referred to, namely, our confused and defective terminology, I need not dwell. "Science," said Condillac, "is a language well made;" and though this is far from being the whole truth, it is an important part of it. In examining medical reports and statistics, it is necessary to bear constantly in mind that, to understand many terms, you must know what the individual writer means by them. When, for example, we find in such statistics a certain number of death attributed to gastro-enteritis, or croup, or scrofula, we have to take into account the country, the period, and the individual author, in order to get even a fair presumption as to what is meant.

The three difficulties which have been referred to, although the most important, are by no means the only causes of the confusion and imperfection of our records.

Prominent among the minor troubles of the investigator are defective or misleading titles; and, in behalf of the readers and bibliographers of the future, I would appeal to authors, and more especially to editors, to pay more attention than many of them do to the matter of titles and indexes. The men to whom your papers are most important, and who will make the best use of them, provided they know of their existence, are for the most part hard workers, busy men, who have a right to demand that their library table shall be provided with properly prepared materials, and not with shapeless lumps.

The editors of transactions of societies, whether these are sent to journals or published in separate form, often commit numerous sins of omission in the matter of titles. The rule should be: that every article which is worth printing is worth a distinct title, which should be as concise as a telegram, and be printed in a special type. If the author do not furnish such a title, it is the editor's business to make it; and he should not be satisfied with such headings as *Clinical Cases*, *Difficult Labor*, *A Remarkable Tumor*, *Case of Wound*, with *Remarks*. The four rules for the preparation of an article for a journal will then be: (1.) Have something to say. (2.) Say it. (3.) Stop as soon as you have said it. (4.) Give the paper a proper title.

Some societies and editors do not seem to appreciate fully their responsibility for the articles which they accept for publication—a responsibility which cannot be altogether avoided by any formal declaration disclaiming it. This is due to the fact that, while the merits of a paper can usually be determined by examination, this is by no means always the case. In every country there are writers and speakers whose statements are received with very great distrust by those best acquainted with them. Supposing these statements to be true, the papers would be of much interest and importance; but the editor should remember that a certain number of readers, and especially those in foreign countries, have no clue to the character of the author, beyond the fact that they find his works in

good company. In medical literature, as in other departments, we find books and papers from men who are either constitutionally incapable of telling the simple literal truth as to their observations and experiments, although they may not write with fixed intention to deceive, or from men who seek to advertise themselves by deliberate falsehoods as to the results of their practice. Such men are usually appreciated at their true value in their immediate neighborhood, and find it necessary to send their communications to distant journals and societies in order to secure publication.

I presume that you are all familiar with the peculiar feeling of distrust which is raised by too complete an explanation. The report of a case in which every symptom observed, and the effect of every remedy given, is fully accounted for, and in which no residual unexplained phenomena appear, is usually suspicious, for it implies either superficial observation, or suppression or distortion of some of the facts. A diagrammatic representation is usually much plainer than a good photograph, but also of much less value as a basis for further work.

No fact is more familiar to this audience than the vast extent of the field of the science of to-day — so vast that few may hope to master more than a small part of it, and yet so closely connected that even the small part cannot be fully grasped without some acquaintance with a much wider field.

But little over a hundred years ago Haller in Göttingen was professor of anatomy, botany, physiology, surgery, and obstetrics, and lecturer on medical jurisprudence. At the same time he was writing one review a week, and summing up existing medical science in his *Bibliotheca*. To-day, any one of these branches requires all the time of the most energetic and learned of our contemporaries; but, on the other hand, the well-educated medical graduate of to-day could give Haller valuable instruction in each of the branches of which he was professor. It is also true, as I have pointed out, that our actual progress is by no means in proportion to the work done, nor as great as these merely quantitative statements would seem to make it.

Science has been termed "the topography of ignorance." From a few elevated points we triangulate vast spaces, enclosing infinite unknown details. We cast the lead and draw up a little sand from abysses we shall never reach with our dredges. If it is true that we understand ourselves but imperfectly in health, it is more signally manifest in disease, where natural actions, imperfectly understood, disturbed in an obscure way by half-seen causes, are creeping and winding along in the dark toward their destined issue, sometimes using our remedies as safe stepping-stones, occasionally, it may be, stumbling over them as obstacles.¹

In days of old, when the profession of medicine, or of a single medical specialty, was an inheritance in certain families, a large part of their knowledge, and the efficiency of their remedies, was thought to depend upon these being kept a profound mystery. Among the precepts of magic there was no more significant one than that which declared that the communication of the formula destroyed its power, and that hence attempts to reveal the secret must always fail. We have changed all that. Every physician hastens to publish his discoveries and special knowledge, and a good many

do the same by that which is not special, or which is not knowledge. For the individual, in a degree, for the nation or the race in a much greater degree, the literature produced is the most enduring memorial. The whole result of civilization has been cynically defined as being, roughly, "three hundred million Chinese, two hundred million natives of India, two hundred million Europeans and North Americans, and a miscellaneous hundred million or two of Central Asians, Malays, South Sea Islanders, etc., and over and above all the rest the library of the British Museum. This is the net result of an indefinitely long struggle between the forces of men and the weights of various kinds in the attempt to move which these forces display themselves."²

And thus, in our great medical libraries, each of the folios or quaint little black-letter pamphlets which mark the first two centuries of printing, or of the cheap and dirty volumes of modern days, with their scrofulous paper and abominable typography, represents to a great extent the life of one of our profession and the fruit of his labors, and it is by the fruit that we know him.

After stating that modern physicists have concluded that the sun is going out, that the earth is falling into the sun, and therefore that it and all things in it will be either fried or frozen, Professor Clifford concludes that "Our interest lies so much with the past as may serve to guide our actions in the present, and with so much of the future as we may hope will be affected by our actions now. Beyond that we do not know and ought not to care. Does this seem to say, Let us eat and drink, for to-morrow we die? Not so, but rather, Let us take hands and help, for this day we are alive together." To this I join a verse from the Talmud which will remind you of the first aphorism of Hippocrates, and is none the worse for that. "The day is short, and work is great, the reward is also great, and the master presses. It is not incumbent on thee to complete the work, but thou must not therefore cease from it."

THE SYSTEMATIC WEIGHING OF INFANTS.³

BY H. C. HAVEN, M. D.

THE desirability of reducing practice to the conditions of an exact science is a postulate of modern medicine; any method of observation conducing to this end is worthy of attention. I therefore make no apology for bringing to your notice a method, homely it is true and possibly familiar to you all, but which it seems to me is of great value in the management of infants, either in health or disease. The systematic weighing of infants substitutes scientific data for personal opinion. Professor Guillot first advised its employment in 1852. It did not come into general use, however, till some time later. In 1866 MM. Blache and Olier, in a memorial presented to the French Academy of Medicine on Infant Mortality and the Means of Preventing It, strongly urged the necessity of regular and frequent weighing. Since that time it has been gradually adopted in France and Germany,

Professor Parrot having done much to popularize it. As far as I have been able to inform myself, although used in this country by a few interested especially in pediatrics, it is seldom employed by the general practitioner, or in many of the institutions devoted to the care of children.

A balance responding to two or three grammes, — almost any in ordinary household use will do this. — a set of weights, preferably metric, are the necessary instruments. The child should be weighed as soon after birth as practicable, being dried and wrapped in a piece of warm flannel. The weight of this should be previously ascertained, or if always used may be disregarded, being a constant factor, and not affecting the results except in the slight original addition. During the first eight or ten days the weighing should be daily. The existence, persistence, and termination of the so-called physiological loss is thus determined. The original weight should be regained from the fifth to the eighth day. After this weekly weighings for the first five months, and later fortnightly, will suffice. The best time is in the morning, when the child's toilet is usually made; this gives slight additional trouble.

The daily gain should be about twenty-five grammes for the first five months, at which time the weight at birth should be doubled; after this its gain gradually decreases to about ten grammes at the end of the fifteenth month, when the initial figures should be quadrupled. These numbers are the mean of a very large number of French observations, and have the demerit of being too exact. In general, however, the average daily gain in the first few months should not be below twenty grammes; if so, the child is badly nourished, sick, or going to be. There are exceptions to this rule, the gain being sometimes less, sometimes greater. It is always, however, in direct proportion to the original weight. If this is very small the gain may be correspondingly small. The technical difficulties of carrying out this method are slight, certainly in any institution they would be, and any mother or nurse of ordinary intelligence can be trusted to secure accurate results.

Its advantages are that it affords absolute knowledge on several points. Is the food, whether milk of mother, nurse, or animal, or some one of the numerous preparations, affording sufficient and proper nutriment to the babe? Is it getting a fair start in life? This question is often the most important and at the same time the most difficult to solve. The scales give us information far more reliable than the intelligence of the mother, the education of the training-school graduate, the experience of the monthly nurse, or even the experience, education, and intelligence presumably combined in the physician himself. Again, in the treatment of disease; are the desired results being attained? This we can tell with certainty; exactly what food, usually the most important of all treatment, is best suited to the child. We can tell in the wasting diseases of children, where often the struggle for life is severe, if we are gaining or losing ground. There are many other advantages I will not go into here. The effect on the mothers of the better class is not, I think, to be despised. It inculcates the habit of systematic observation of their children and correct deductions therefrom. It enforces the all-important connection between the diet and the health of the child; a truism, an axiom to the physician, unfortunately not to many even of the most intelligent mothers. In dispensary

practice, who that has suffered from the maddening prolixity or the sullen ignorance of the average mother of that class, would not be rejoiced to get, as he can by this method, in a moment's time, some satisfactory and reliable evidence as to the condition of the child, the success of his treatment, and how far his dietetic instructions have been followed. I quote from M. Boudet: —

"Is it not fortunate that we can apply to the oftentimes so difficult appreciation of the symptoms of sickness, convalescence, and health one of the exact methods which are the privilege of the physical sciences. As exact is the balance, so significant is it in revealing the health of the infant and the influence of the quality and quantity of its nourishment, the state of health of the nurse; the exact and frequent determination of its weight faithfully translates the onward and backward march of its development. I am astonished that this system has not come into more general use. How much superior are the indications of the balance in comparison with even the most experienced eye, in recognizing emaciation or the reverse. I do not speak of the difficulties of the system; it is not a serious objection.

I subjoin some weight charts, which will show better than words how accurately the balance indicates the condition of the child.

A METHOD OF DISCOVERING BY ACUPUNCTURE AND ELECTRICITY THE EXACT LOCATION OF BULLETS OR OTHER PIECES OF METAL IN THE BODY.

BY JOHN VANSANT, M. D.,

Surgeon United States Marine Hospital Service.

In gun-shot wounds, when there is no opening of exit, and in other cases where pieces of metal may have been lodged within the body, the difficulty and uncertainty of discovering the exact location of the bullet or metallic mass is often great, as is well known. Projectiles are so easily deflected from a straight path, and made to take such devious courses by apparently trifling obstructions in the body, that it is frequently unsafe or impossible to follow them along their track to their resting place. But if this can be done prudently, in such cases of deflection, by flexible probes of ordinary construction conveying information by the sense of touch, or by those fitted at the inserted end with some device to bring away small particles of the metal by friction thereon, or by those containing wires, insulated except at their points, and intended to give an electric signal upon contact with a bullet, there will still be doubt as to the precise location of the object touched, even though its metallic nature may be ascertained, because of the uncertain direction of the probe, due to its flexibility and bendings. The patient's sensations will then be the chief guide, and these will usually indicate, independently of any probing, the place *near which* a metallic mass may have lodged, whilst palpation, pain on pressure, and local discoloration of the skin will each furnish, at times, confirmatory evidence.

To remove all doubt in the matter it will only be necessary to introduce a slender steel wire or needle, by the shortest route, directly through the tissues from the outside down to the place where the piece of

metal is supposed to lie. If the point of the needle come in contact with some obstruction, presumed to be the metal, then allow this needle to remain, and insert in the same way a second similar needle near to the first one, but not touching it, and cause the ends of the two needles to press firmly against the obstruction; then connect the exterior ends of the needles by wires, in a circuit, with a small tolerably sensitive galvanometer, and *one* very small galvanic cell. If the obstruction be metallic this will be shown immediately by a deflection of the index of the galvanometer, but if not metallic then no such deflection will occur, for the weak current from one cell will not pass sufficiently through even the thinnest stratum of animal tissue to sensibly affect the galvanometer. Neither will such a feeble current heat the inserted needles in case their points should rest in contact with a bullet or other piece of metal.

The needles or wires employed for this kind of acupuncture should be as slender and delicate as they can be and have the necessary rigidity to enter the softer tissues. They should not be highly tempered, but should be capable of bending without breaking, and they require no insulation.

If the bullet be missed at the first insertion other trials may be made until satisfactory results be obtained, for it is well known that fine needles can be introduced with impunity into any of the tissues and almost all of the organs of the body. Only a few days ago I made positive a diagnosis of "aortic aneurism below the diaphragm" by means of a hypodermic syringe having a long slender needle, using the instrument as an aspirator. Not the slightest ill effect followed. These needles are often inserted into the liver, testes, and other organs without any bad results. The needles, however, should be as slender as consistent with necessary strength.

A galvanic cell composed of a rod of malleable iron and another of amalgamated zinc, each about one eighth inch diameter by about three inches long, passed through the cork of a small vial or test tube, and immersed in diluted sulphuric acid, will furnish a current of ample strength.

This combination of acupuncture needles with a galvanometer and weak battery can be used very effectively, also, to supplement the "electric balance," like that recently employed in the endeavors to determine the location of the bullet in the body of the wounded President of the United States.

The latter instrument discloses the presence of a metallic mass in the tissues, and its approximate distance from the surface, provided the size and shape of the mass and the mode in which its surfaces present themselves be known. But these are the very data usually unknown. The acupuncture needles with galvanometer and feeble current reveal the exact location of the mass, and the needles can be used as a guide for making an incision to extract it, when such operative procedure may be requisite.

UNITED STATES MARINE HOSPITAL, {
PORT OF BOSTON, MASS., August 10, 1881. }

—The seventh annual meeting of the Indiana, Illinois, and Kentucky Tri-State Medical Society will be held in the city of St. Louis, Mo., Tuesday, Wednesday, and Thursday, October 25, 26, and 27, 1881.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.¹

BY F. L. KNIGHT, M. D.

PARALYSIS OF THE POSTERIOR CRICO-ARYTENOID MUSCLES OF THE LARYNX.

DR. FELIX SEMON has an exceedingly interesting article² on the proclivity of the abductor fibres of the recurrent laryngeal nerve to become affected sooner than the adductor fibres, or even exclusively, in case of undoubted central or peripheral injury or disease of the roots or trunks of the pneumogastric, spinal accessory, or recurrent nerves.

This curious and important fact is by no means entirely new or unknown. The allusions to it, however, have usually been incidental, and intended rather to explain, by some hypothesis or other, what is considered a pathological curiosity, than to come to certain definite and general conclusions. Its importance is, Dr. Semon hopes to show, so great, especially with regard to the diagnosis of diseases of the brain and chest, in which the laryngeal affection plays the rôle of an important, sometimes pathognomonic, symptom, that it is justifiable and desirable that this question should be once more and separately brought before those who have the opportunity of either corroborating or correcting his statements and conclusions. The question at issue stands thus: It is well known that with the exception of the crico-thyroid muscles (the tensors of the glottis), which are supplied by the superior laryngeal nerve, all the other laryngeal muscles, adductors as well as abductors, receive their motor innervation from the recurrent laryngeal nerve. But this fact, simple and natural as it seems to be to all of us who are accustomed to look at it as to a self-understood matter, nevertheless invites a consideration concerning a very interesting, very important, and wholly unsolved question, namely, as to the manner in which this small nerve accomplishes its most complicated and intricate functions.

Quite apart from the delicacy of the mechanism of the vocal apparatus, over which the recurrent nerve, in conjunction with the superior laryngeal nerve, has to preside, the natural question must at once present itself to our mind: In what way are the diametrically opposed functions of opening and closing the glottis accomplished, over which, as far as we know at present, the recurrent nerve alone presides? Are we to believe that the nerve is, in fact, a homogeneous one, but that different stimuli, or stimuli coming from different centres, can set up in its root different forces, conducted through the same nerve fibres, and resulting at one time in a general involuntary contraction of the abductor muscles, and at another in the almost always voluntary contraction of their antagonists? Or, are we to suppose that, though the nerve is apparently homogeneous, it consists in reality of bundles of strictly differentiated fibres, bound together simply by a common nerve-sheath, and actually differentiated throughout their peripheral course, in fact having ganglionic centres of their own? Semon thinks pathological facts strongly support the latter hypothesis. It will be seen that even this hypothesis is by no means sufficient to explain all the pathological phenomena introduced in the paper.

A study of the anatomy of the inferior laryngeal

¹ Concluded from page 197.

² Archives of Laryngology, vol. ii., No. 3.

nerve shows that the individual muscular branches are only given off close to the larynx. Considering this anatomical fact, and another equally plain one, namely, that the diameter of the trunk of the nerve is a very small one (one mm. when close to the larynx, according to Luschka), it is very tempting to draw at once the conclusions alluded to above, namely: (1.) That any lesion or disease affecting the nerve from its centre to the spot where it gives off the first branch for the posterior crico-arytenoid muscle, must of necessity affect all the laryngeal muscles (with the exception, of course, of the crico-thyroid muscles, and perhaps of the epiglottidean muscles). (2.) That, on the other hand, any impairment of mobility, if not due to mechanical or myopathic influences, of a single one or some of the laryngeal muscles seems to point out clearly that the cause of this impairment must be a local one, due to injury or disease of the respective nerve twigs. These conclusions cannot be rejected *a priori* as unreasonable. The anatomical facts seem to support them strongly, and although it was known at a very early period in laryngological studies that the abductor and adductor muscles could become separately affected, yet the possibility has been emphatically denied that such a partial paralysis could be due to either central causes or affections of the main nerve trunks.

This view is fallacious in consequence of the omission of a very simple but important consideration, namely, that we must distinguish between a complete and an incomplete as well as between an acute and a gradually progressive lesion of the nerve. If we have an acute complete lesion, such as is produced by transverse cutting of the pneumogastric or recurrent nerves, experiments on animals, as well as occasional observations on human beings, have shown beyond doubt that the consequences are such as would be expected theoretically, namely, total loss of the functions of all the laryngeal muscles (with the exception of the crico-thyroid). Matters, however, become entirely different, if we have to deal with either an incomplete acute or an incomplete gradually progressive lesion. The former of these two conditions is certainly an extremely rare one in practice, though it can be easily produced by experiment, the latter, on the other hand, is the form which is not only practically the most important, but almost the only one which occurs in reality. If we believed that all the recurrent nerves were identical and not differentiated, but that different stimuli, coming from either the same or from different centres, could be transmitted through them, it seems to Semon that in every case in which there is an incomplete impairment affecting the roots or trunks of the spinal accessory, pneumogastric, or recurrent nerves, one could reasonably expect one and the same sequence only, namely, diminution of all the functions of all the laryngeal muscles supplied with motor fibres by the recurrent laryngeal nerve, and this diminution in proportion to the number and strength of the fibres disabled by the disease-producing cause. In other words, every paralysis of the recurrent nerve, unless acute and complete from its commencement, ought to begin with loss of the adductive as well of the abductive power, and this equal impairment should progress *pari passu* with the disablement of the still conducting fibres, until at last, all of them having become devoid of conducting elements by some external cause or internal retrogressive metamorphosis, the stage of complete paralysis of the nerve with immobility of the corresponding vocal cord in the cadaveric position it attained. Dr.

Semon has never seen a case in which the symptoms developed in this way. If in reality all the fibres of the recurrent nerve were identical, the loss of some of them by any pathological process must, as I have tried to explain, under all circumstances be followed by the same consequences. The intensity of these consequences might vary according to the number of disabled fibres, and perhaps according to the rapidity of the pathological process; but in all cases the differences could only be quantitative, and never qualitative. In other words, if this hypothesis were correct, it would not admit of a single exception to the rule. A single exception, a single good observation, proving that in a case of gradually progressive paralysis of the roots or the trunks of the accessory, pneumogastric, and recurrent nerves, one set of laryngeal muscles was either before their antagonist, or even exclusively paralyzed, annihilates the entire hypothesis of the homogeneousness of the filament of the recurrent nerve, for if they were really homogeneous, the laryngeal muscles could never be separately affected by a lesion involving the trunk of the nerve itself. Now we have not one, nor a few, but many cases on record, in which clinical observation and the post-mortem examination have actually shown that, although the disease-producing cause acted upon the whole nerve-trunk, yet one set of laryngeal muscles only became affected, or one much more than the other. Such cases have occurred to every observer of much experience. Dr. Semon does not think there is any possibility of reconciling this positively ascertained fact with the theory of the homogeneousness of the recurrent nerve, and therefore believed that this theory must be completely given up.

The second hypothesis appears the more probable, and one *a priori* harmonizing much more with the complexity and delicacy of the vocal functions of the laryngeal muscles, namely, that the filaments of the recurrent nerve are strictly differentiated throughout the course of the pneumogastric nerve, and even possess ganglionic centres of their own. The adoption of this hypothesis at once gives a clue to the explanation of the frequent clinical observations, that in cases of intrinsic nerve disease as well as of external mischief to the nerve, and in cases of central as well as of peripheral lesion, one set of the muscles is earlier affected than the other or even exclusively. If, for instance, a disseminated sclerotic affection of the brain should happen to affect those ganglionic centres only which form the nuclei of the abductor filaments of the recurrent nerve; if a tumor of the neck should happen to press on those nerve fibres only which supply the crico-arytenoides lateralis, the thyro-arytenoides, and the arytenoides proprius muscles (this latter example has been chosen merely for the sake of illustration; as far as known to the author no such case has been reported) it would not need further explanation to prove that in the first instance we would see, laryngoscopically, the vocal cords not in the cadaveric but in the phonatory position, because the posterior crico-arytenoid muscles only were paralyzed, and that, on the other hand, in the second instance we would see the glottis widely open, and meet with complete aphonia in consequence of the inability of the solely paralyzed adductor muscles to bring the vocal cords together for the purpose of phonation. In each of these two cases this state of things could remain stationary (namely, if the pathological process occasioning the paralysis came to a standstill) or could lead to com-

plete paralysis with its consequences (namely, if the antagonistic centres or fibres, which were left free at the beginning, became also affected later on).

It would seem, then, that the earlier symptoms in cases of incomplete, slowly progressing paralysis entirely depended upon the question which fibres have been accidentally first attacked, and the natural conclusion would be that we sometimes should expect early lesion of the abductors, at others of the adductors.

The author then introduces twenty-two cases showing that isolated paralysis of the posterior erico-arytenoid muscles was the result of disease or injury to the centres and nerve-trunks, or that at any rate the paralysis of these muscles was earlier, and respectively more developed than that of their antagonists. This number cannot be compensated by an equal or approximately equal number of observations proving the occurrence of a primary affection of the adductor fibres under similar circumstances, and indeed the author has not been able to find, in the whole range of laryngeal literature known to him, a single case in which primary organic disease of the brain or of the nerve-trunks was proved by clinical observation or the result of the post-mortem examination to have been the cause of isolated paralyses of the adductors!

The cause of the proclivity of the abductor fibres to be affected sooner than the adductor, or exclusively, is difficult at present to explain satisfactorily. Semon holds that the theory of the uniformly central origin of this paralysis is untenable in the face of the authenticated cases of paralysis and degeneration of these muscles (the abductors) in consequence of disease of, or pressure upon, the nerve-trunks.

Several hypotheses might be made and have been made to explain this peculiar proclivity, namely:—

(1.) That the anatomical distribution of the fibres of the recurrent nerve may be a concentric one, and that the abductor fibres may be situated in the periphery of the nerve, that is, most exposed to all external injuries.

(2.) That there may be a specific vulnerability of the abductor filaments, or what would amount practically to the same thing, that even in cases of partial disablement of the adductor filaments, the remaining healthy adductor fibres might conduct all the nerve force emanating from the adductor centres to the adductor muscles.

(3.) That possibly the adductors receive an increment of nerve force from the superior laryngeal nerve.

All of these hypotheses are open to certain objections, and none of them seem to the author to offer a really satisfactory and plausible explanation, the time for which, he thinks, has not yet arrived. Semons thinks, before all, by numerous further contributions, the fact should receive further corroborative evidence that *there is a proclivity of the abductor fibres of the recurrent nerve to succumb to pathological influences affecting the roots and trunk of the motor nerves of the larynx.*

Quite apart from the great intrinsic anatomical and physiological interest of the question, its affirmative reply would entitle us to lay down the following practical rule: Immobility of one or of both the vocal cords in the phonatory position — if not occasioned by mechanical impairments or myopathic affection — invites to a consideration of all the possibilities which may produce paralysis of the entire recurrent nerve;

immobility in the position of deep inspiration — if not occasioned by mechanical impairments or myopathic affection — is much more likely to be due to either a functional or a local neurosis, that is, an affection produced by local disease of the adductor twigs of the recurrent nerve.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DRS. DOE AND MASON.

REPORTED BY DR. WITHERINGTON, HOUSE SURGEON.

SIX CASES OF TYPHUS FEVER.

ON April 13th a family of six persons was admitted to the hospital. They were found in a house on Meander Street, of bad hygienic condition. They were all lying about in a dull, stupid condition, unable to do anything for themselves, and all, with the exception of the infant, appeared to be suffering from the same symptoms. The family was composed of the following persons: (1) Mrs. L., aged fifty-four; her daughters, (2) Susie, aged twenty-nine, and (3) Louise, aged twenty-five; her grandchildren, (4) Mary, aged eleven, (5) Louis, aged six, also Willie, aged sixteen months (not sick); (6) Lewis, another member of the family, entered later.

The history, so far as it could be obtained, was as follows: The family had always been healthy. The husband and father had returned home, after an absence of four years, about March 23d. Most of this time he had been at sea, but had recently landed at New York. While there he was taken sick, and returned to his family to be taken care of. The nature of his illness is not known, but on reaching home he complained of headache and dizziness, and on attempting to walk would fall. He was unable to go about much, but was not confined to his bed. After ten days he began to improve, and at the time his family were taken sick considered himself well.

Soon after the father's return Louise began to complain of headache, languor, etc., but kept about her work. On April 3d she took to her bed after a severe chill, complaining of dizziness, intense headache, and ringing in the ears. There was no pain in any other part of the body. About two days later, April 5th, Louis, the little boy, was taken sick with very similar symptoms, which obliged him to go to bed. No prodromata reported. April 7th, Susie, who had been at her work until the night before in her usual good health, was seized with headache and dizziness without other subjective symptoms, but was so prostrated that she had to take to bed. Later in the same day she was followed by Mary, who had kept up till that time, though she had had a headache for three days previously. The mother was the last of the family to yield, though she began to feel badly the evening of the 6th. By lying in bed a portion of the time she succeeded in partially caring for the others until the morning of the 13th, when she found herself unable to rise.

Willie, the infant, who entered simply for care, was a large, healthy boy, and presented no symptoms of any disease. But, as will be seen, with this exception all the members of the household were affected.

Five days later another member of the family, but not of the household, entered the hospital. He, Lewis, aged twenty-five, is a brother of the two young women,

is married, and lives in Jamaica Plain. On the night of his father's return the son spent the evening with him, and remembers that he smoked his father's pipe.

Ten days later he repeated his visit. Two days after this, April 5th, he was attacked with headache and vertigo, accompanied with a chilly feeling and vomiting. He entered on the twelfth day of his sickness, and allowing for the difference in the stage of the disease his condition was exactly similar to that of the others.

All these patients had a dull, stupid appearance. All complained chiefly of headache with dizziness and staggering if they attempted to walk. None of them had any abdominal pain or distention, though in one case there is record of gurgling with tenderness in the right iliac fossa. There was no diarrhoea. In four cases the bowels were constipated, in two regular. In all the cases the tongue was coated, and the face flushed. The temperatures on entrance varied from 102° F. to 104.2° F. The clinical charts, published herewith are numbered according to the arrangement of the names where they are first given.

In the course of the fever active delirium was present in three of the cases. It was usually of a pleasant character. In one case the prattling and singing were nearly constant for several days, and were accompanied by almost incessant movements of the hands. Retention of urine was observed in most of the cases.

An eruption appeared in three of the cases, the

three young adults, who were the sickest of the family. This eruption was pretty well scattered over the trunk, and all the extremities, but was most abundant on the abdomen and chest. It was for the most part macular, but some of the spots were slightly raised. The color was a dull, dark red, and did not wholly disappear on pressure. No petechiae were observed. In one case rose spots are reported intermixed among the other spots.

The period at which the eruption appeared is known definitely in only one case, in which it was on the fifth day. Its disappearance, which was gradual, was completed at about the establishment of convalescence in all the cases. In addition to the three well-marked cases of eruption, the mother, whose skin was considerably freckled and stained, had a few reddish spots here and there, which, though not of themselves at all characteristic, yet taken in connection with the other cases were worthy of note. The skin of the children remained perfectly clear throughout.

Complications. Lewis (6) was taken with facial erysipelas after his fever had subsided and he had sat up one day. The attack was moderately severe, and ran a course of about nine days.

Mrs. L. (1) had a painful swelling of the submaxillary gland on the left side, followed, in a few days, by a similar swelling on the right side. These underwent resolution, and disappeared in about a week.

Contagion. No other case of the disease developed in the hospital. A patient, however, who occupied a bed adjoining one of the cases for a few days before the latter was removed to the isolating ward, and who soon after left the hospital, was taken sick a day or two after her discharge with what the attending physician pronounced typhus fever. No other cases occurred in Boston.

The course of the disease, reckoning it in each case from the day the patient took to his bed till that on which he first sat up, varied from eleven days in the case of Mary to about four weeks in the case of Susie. The average of all the cases was twenty-one days. This does not include the duration of the erysipelas, which developed after the patient had sat up, but does include that of the adenitis, which came on before the patient had left her bed.

Remarks. As typhus fever is a rare disease in this vicinity, and its prevalence in neighboring cities and in foreign countries from which many thousand immigrants are now arriving, concerns the public health, these cases are reported as being of local interest. Although the nature of the affection was suspected at the outset, the absence of the characteristic eruption in half of the cases, and the comparatively mild form of the disease, prevented an immediate positive diagnosis. The usual symptoms of typhoid fever, however, were wanting, and the temperature curves are instructive.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. M. RICHARDSON, M. D., SECRETARY.

APRIL 18, 1881. DR. H. C. HAVEN read a paper on the

SYSTEMATIC WEIGHING OF INFANTS.

which will be found on page 222 of this number of the JOURNAL.

In reply to Dr. Webber, Dr. Haven said with regard to the prognosis, that these charts afford a better means than any other. It cannot strictly be said that a rapid diminution in weight makes the prognosis grave. There are no strict rules to be applied.

DR. DRAPER spoke of the value of such observations as the reader had illustrated in determining more accurately the weight of children at birth. Each observation gives us new and valuable information. The normal weight of the new-born child is important in a medico-legal way also. About thirty-five hundred grammes is about normal all over the world.

DR. BUCKINGHAM asked if there was any difference in the weight of children of primiparae and pluriparae. It is said by a German writer that the milk with the first child is less abundant than at later births.

DR. HAVEN replied that not only is the initial weight of the first-born child under the average, but their daily increase is also less. Observations taken in France show that the children of primiparae increase less rapidly in weight than those of pluriparae, the milk of the mother being not only less nourishing, but also less abundant.

DR. MINOT thought it important to note other things at the same time with variations in weight, such as age and health of parents. Another interesting point would be a comparison of the weights of children fed upon different foods. The comparative value of the different forms of infants' food could in this way be ascertained better than in any other. It is important to know what is the best artificial food. Dr. Minot had seen, this winter, in a child a curious condition of things. It was thirteen months old, and unable to use its legs. The reflex function of legs was lost. The child looked intelligent, and could speak a little. It was found that it had been fed upon condensed milk. It was put first upon cow's milk and then upon Mellin's Food. Improvement was immediate. It was soon able to move its legs, and before long could do so very well indeed, till it was able to stand and walk by pushing a chair before it. No medicine was used. The case looked very much like infantile paralysis. There was no observation of the daily weighing, though it would have been very interesting.

DR. PORTER reported the following case:—

INTESTINAL OBSTRUCTION; REGULAR DEJECTIONS FOR FOURTEEN DAYS BEFORE DEATH; AUTOPSY; TYPHLITIS; ULCER OF CECUM OPENING INTO PERITONEAL CAVITY; PERITONITIS.

M. C., the patient, a man of twenty-eight, had been in good health until Thursday, March 17th, then, in consequence of exposure to cold he developed acute cystitis. Friday, 18th, as his bowels had not been opened the previous day, he took, without the advice of his physician, a number of Schenk's mandrake pills, about half a dozen. In consequence of these he had several violent and painful dejections during the night, and the next morning he was seized with intense pain, its worst seat being on the right side, at about the junction of the iliac and hypochondriac regions. Sunday, 20th, the pain had increased in severity, and extended over the whole abdomen; he was unable to retain any nourishment; there had been no dejection since those induced by the pills. Monday, 21st, he was admitted to the hospital. There was then tenderness over the whole abdomen, but most marked on the right side,

and just above the pubes; extreme restlessness; great thirst; inability to retain nourishment. As it was not until he had been in the house a week that a possible origin for the trouble was learned from his family, a diagnosis was not clearly made on entrance. He was ordered hot fomentations, nutrient enemata, and opium pro re nata.

March 22d. From the patient's statement that there had been constipation for some days it was thought that intussusception might be the cause, and copious enemata were given, without effect, however.

March 23d. There was so much suffering from the nutrient enemata, principally because of hemorrhoids from the violent straining of the previous week, they were omitted, and one drachm doses of milk and soda water given hourly. This was the first thing tolerated by the stomach for four days. To keep him quiet he required three grains of opium hourly. Tympanites was now quite marked.

March 24th, the sixth day from his attack. During the night the quantity of milk and soda was increased to half an ounce hourly; when this caused any nausea the next dose was omitted. An enema as copious as he could endure was tried again, but produced no movement.

March 25th and 26th. No change except that he was growing weaker.

March 27th, ninth day. Tympanites very much increased; passed no flatus; took one ounce milk and soda hourly.

March 28th, tenth day. To-day it was first known that the patient had subjected himself to the violent purgative mentioned at the beginning of the case. His condition was steadily growing worse; pain was excessive, and in addition to one half grain morphia suppositories he required frequent hypodermics of one fourth grain; nausea frequently prevented him from taking his milk.

March 30, twelfth day. Tympanites greatly impeded respiration; no nourishment was being taken, and the patient was very low indeed. To give relief to the over-distended intestines three punctures were made in the linea alba with the aspirator needle, giving vent to a large amount of gas. A puncture was then made over a prominent place in the transverse colon, at its left extremity, and over the descending colon just above the sigmoid flexure. As before gas escaped through the needles for a few minutes, then came a discharge of liquid intestinal contents. For more than an hour these two tubes discharged this fluid. At the end of that time the abdomen had relaxed to nearly its normal tension; the patient was greatly relieved from pain, and the respirations were easy. At the close of the operation intestinal movements could be heard, and during the night flatus was freely passed, the first time for twelve days.

March 31st, thirteenth day. The patient was very comfortable. There was no return of tympanitis and no pain; milk and soda were freely taken, and solid food requested; there was one defecation early in the morning, not large in amount, consisting of the same kind of fluid as was evacuated through the needles.

April 1st, fourteenth day. Within thirty-six hours patient has had fifteen movements, some of them containing a few small scybalæ; there has been improvement in every symptom, and since that date the bowels have been regular, and in no way has there been any intestinal disturbance.

April 3d, sixteenth day. Took solid food; sat up in

bed; stool daily of perfectly normal character; slight swelling noticed over parotid gland.

April 4th, seventeenth day. Swelling had increased, and was quite painful. From this date until the 8th there was no change in his condition except that the parotid abscess increased, and by the surrounding œdema obstructed the œsophagus so that swallowing was impossible.

April 8th, twenty-first day. Fluctuation just anterior to the ear. The abscess was opened, a large amount of pus escaping.

April 9th, twenty-second day. Pus in considerable quantities was noticed in sputum, which, up to this time, had been only mucous; the quantity of pus expectorated increased daily; the discharge from the parotid abscess ceased entirely.

April 12th, twenty-fifth day. Until this date the patient seemed gaining ground every day. He took large quantities of nourishment and stimulants, but quite suddenly on this day there was a change for the worse. He seemed weak, his appetite failed, and cough increased.

April 15th, twenty-eighth day. From this time until he died there was a constant failure in strength, but absolutely no local symptoms; his bowels acted every day with well-formed dejections; there was no abdominal pain or tenderness; on the day of his death he suffered from dyspnoea, but not previously.

Autopsy by Dr. Fitz.

On opening the anterior abdominal wall a subcutaneous abscess containing about a drachm of thick pus was found corresponding with the site of an abdominal puncture.

Heart. Right side distended with freshly clotted blood. Valves and cavities normal. Muscular substance opaque. Pericardial surface normal.

Lungs. Posterior portion both lobes of the left lung distended, heavy, dense, corresponding pleural surface opaque, injected with occasional hæmorrhagic spots, and delicate patches of recent false membrane. On section through the lung the surface was granular in the affected portions, dark-red, and friable. The right lung was adherent to the thoracic wall by recent adhesions, and was extensively infiltrated by granular material, the cut surface mottled with spots of yellow, from which puriform material exuded on pressure. Soft, yellow, curdy substance was frequently present in the smaller bronchi.

Spleen, twice normal size, soft on section, reddish-gray, follicles indistinct.

Kidneys enlarged; capsule easily detached; on section cotyledons gray and opaque; opacity of convoluted tubes.

Bladder normal.

Liver enlarged at least one third; reddish-gray color; a superficial abscess, large as a walnut, in the upper part of the right lobe, the diaphragm forming its upper wall, and sloughing over it. On section reddish-gray, opaque parenchyma with distinct lobular divisions.

The pelvic cavity was shut off from general peritoneal cavity by recent adhesions between its walls and coils of intestines, and contained a quart of dirty gray, opaque, and offensive pus. A circumscribed abscess as large as the first was found about the cecum. Its cavity contained pus and faecal matter and its walls were shreddy. Three openings in the vermiform appendix communicated with this cavity: one at the end of appendix with sloughing margin; two, each one

fourth of an inch in diameter, with slaty-blue border, about one half an inch below the opening into the caecum. The mucous membrane at the head of the caecum, over a patch nearly as large as the palm of the hand, was deeply and irregularly ulcerated, and an opening between the pericecal abscess and the interior of the caecum was found, one inch in diameter. The destruction of tissue around it was more extensive at the outside of the intestine, and there was no loss of mucous membrane beyond the margin of the opening. The mucous membrane of the stomach was thickened and opaque, mammillated. That of the intestines was also thickened and opaque, the follicle enlarged, and two of Peyer's patches contained several small ulcers.

Diagnosis.—Typhlo-enteritis with perforate perityphlitis, encysted peritonitis, double fibrinous pneumonia, acute abscess of liver, acute splenic tumor, cloudy swelling of heart, liver, and kidneys.

Dr. Minot read the following cases, the accompanying specimens being shown by Dr. Whitney.

PHLEBITIS ORIGINATING IN INFLAMMATION OF THE APPENDIX CECI.

The patient was a vocalist by profession, thirty-three years old. He had twice suffered from intermittent fever, many years ago, in Louisville, but his health had been good since then. In March, 1880, he had an attack of abdominal pain, with vomiting, lasting a day; and afterwards a similar attack, but more severe, and accompanied with chills. The present attack began, without obvious cause, March 21, 1881, with pain in the abdomen followed by vomiting and a chill. For several days afterwards he had two or three chills daily, at irregular intervals, followed by fever and free perspiration. He entered the Massachusetts General Hospital, under the care of Dr. Minot, March 10th. No enlargement of the liver or spleen could be felt. There was tenderness in the epigastrium; the urine contained a trace of albumen with hyaline and granular casts. Temperature, 102° ; pulse 95. For several days he was treated with large doses of quinine, but without any benefit, the chills recurring with severity, and the temperature rising at times to 107° . April 5th, there was much tenderness in the right iliac region. The discharges became involuntary, the patient failed rapidly, became comatose, and died on the evening of April 13th. There was no œdema anywhere, and no evidence of thoracic disease.

The following are the chief points of interest in the account of the autopsy by Dr. Fitz. On the upper surface of the lower lobe of the right lung, in the transverse fissure, was a superficial abscess, of the size of a pea; the pleura covering this part of the lung was ecchymosed and roughened, with a delicate layer of recent false membrane. Spleen slightly increased in size, normal in color and consistency. The kidneys presented a slight opacity in the region of the convoluted tubes, otherwise not remarkable. The small intestines were injected, several coils in the right lumbar region were attached to the meso-colon by recent adhesions, and on detaching these a circumscribed purulent peritonitis was observed, the cavity containing half an ounce of pus. The mesentery attached to the caecum was extensively infiltrated with pus. Surrounding the vermiform appendix, and connected with its interior by a small opening, was a trabeculated cavity of the size of a plum, with shreddy walls, which communicated with the caecum by an opening large enough

to admit the tip of the little finger. The mucous membrane of the appendix was yellow and opaque, apparently necrosed. The radicles of the portal vein in the mesentery, especially those arising from the region of the caecum, were dilated, and distended with pus. In spots these collections of pus approached the peritoneal surface so closely as to produce a soft, yellow nodule, the peritoneum in their vicinity being injected, ecchymosed, and roughened. In following certain of the branches of the portal vein towards the periphery fresh thrombi were found beyond the purulent ones. The purulent masses extended up to the trunk of the portal vein, and followed its ramifications into the liver. In the portal vein outside the liver the pus was contained within a shell of adherent thrombus, often separated from the smooth wall by a free space. Liver not enlarged; on section, a general injection of its tissue was apparent, with numerous circumscribed collections of pus either within or surrounding the divided branches of the portal vein. These varied in size from that of a pin's head to that of the primary branches of the vein, were often grouped in clusters, and represented either abscesses or sections of softened thrombi. The mucous membrane of the large intestine was swollen and injected, with occasional small nodules, which on section were found to be collections of puriform material in the branches of the mesenteric vein.

MEETING OF THE AMERICAN DERMATOLOGICAL ASSOCIATION.

The members of the American Dermatological Association met for their fifth annual meeting at the Ocean House, Newport, on Tuesday, August 30th. The officers for the past year were: president, Dr. J. Nevins Hyde, of Chicago; vice-presidents, Drs. E. Wigglesworth, of Boston, and C. Heitzman, of New York; secretary, Dr. Arthur Van Harlingen, of Philadelphia; treasurer, Dr. I. E. Atkinson, of Baltimore.

After a business meeting with closed doors, the regular morning session commenced with the annual address by the president on

PERIODICAL DERMATOLOGICAL LITERATURE,

of which a very interesting and full account was given, followed by an index of papers in journals devoted to dermatology.

Dr. James C. White, of Boston, presented a paper on the

LIMITATIONS OF INTERNAL THERAPY IN SKIN DISEASES.

He showed that the number of drugs that we are justified in regarding as possessed of true *specific* action on cutaneous disease is very small, being limited to mercury, iodine, and arsenic. He most thoroughly went through all the classes of skin diseases as adopted in the Association's system of classification, and showed that with the exceptions above mentioned we had no positive proof of any benefit to the skin disease as such from the administration of any known drug or substance, although often we may indirectly benefit the disease by correcting evident disturbance of the general health when such exists. He favored the thorough and scientific investigation of this subject by a committee of the Association.

Dr. C. Heitzman, of New York, gave an address on some points in the minute anatomy of the skin, more

especially with regard to the development and anatomy of the hair and hair follicle, with regard to which some entirely new and original facts were laid before the society. The nature of the communication, it being the result of long-extended microscopical investigation, precluded discussion, properly speaking, but the numerous questions asked by several of the members showed how interesting and clear these points of minute cutaneous anatomy had been made to them.

The evening session of the 30th was opened by Dr. Van Harlingen with a report of a case of Lymphangioma Cutis Multiplex, which was followed by a paper by Dr. Dühring, of Philadelphia, on the Small Pustular Scrofuloderm, based on three carefully observed cases. After an interesting discussion on these communications the meeting was adjourned to the following morning.

At the business meeting of the 31st the following officers were elected for the ensuing year: president, Dr. J. Nevins Hyde; vice-presidents, Drs. Fix, of New York, and Hardaway, of St. Louis; secretary, Dr. Van Harlingen, of Philadelphia; treasurer, Dr. Atkinson, of Baltimore.

The regular morning session was opened by the chairman of the committee on statistics, Dr. J. C. White, who reported the statistical tables of cases of skin disease occurring in dispensary and private practice, received from the various sections into which the country is divided for this purpose. These statistics are becoming more valuable each year. For the present year the cases tabulated number over eleven thousand. Dr. White's report included the statistics of leprosy for the present year, with a valuable history by Dr. Graham, of Toronto, of the lazarette at Tracadie, New Brunswick.

Dr. Atkinson then read a case of

TUBERCULAR LEPROSY

occurring in Baltimore, which at first, on the most thorough investigation, seemed to be of necessity sporadic in nature. He discovered later, however, that one of the only other two cases of the disease that had ever existed in Baltimore, so far as he could find out, had lived for a time in the house next his patient, and that they had seen each other. Dr. Atkinson also read a paper for Dr. Bernann, who had examined specimens of diseased tissue from this case, and showed sections which were exceedingly interesting, as Dr. Bernann had succeeded in showing objects which seem to be the same as what is claimed to be the *Bacillus Leprosus*.

Dr. Hyde reported a case of Acute Tubercular Leprosy running through its acute stage in five to six months. He closed the morning session by reading an elaborate article by Dr. H. D. Schmidt, of New Orleans, on the Pathological Anatomy of Leprosy, in which the microscopic appearances were most thoroughly reported.

The greater part of the evening session was taken up by a most earnest discussion of the papers read during the morning, and the meeting was adjourned after the reading of a paper by Dr. Wiggleworth on the subject of

LOCAL ULCEERATIONS OF CONSTITUTIONAL ORIGIN.

which he suggested, namely the local treatment of such lesions by calomel and iodoterm, combined, of course, with appropriate constitutional treatment.

At the morning session of September 1st Dr. Heitz-

mann gave an account of his clinical experience in the use of the solution of oxy-sulphuret of calcium (Vleming's solution), which was extremely interesting, and followed by a general discussion. Dr. Heitzmann's paper on

ELECTROLYSIS FOR EPILATION

was also read at this meeting. It was a report of very successful destruction of hair by this method, a very large number of hairs having been treated, of which relatively few returned. In three weeks it was evident which hairs had not been destroyed, and a second operative procedure was held. At the end of three months only six hairs were visible. Drs. White and Dühring spoke of the success this procedure had had in their hands.

Many fine specimens were shown at this meeting.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

S. W. LANGMAID, SECRETARY.

SURGICAL SECTION.

APRIL 15, 1881. DR. R. M. HODGES in the chair.

DR. E. H. BRADFORD spoke of the operation of

RESECTION OF THE TARSUS IN CLUB-FOOT.

and illustrated the method.

DR. HODGES showed several casts illustrating the good results obtained in spite of the small bones being removed to a very considerable extent. He said there were three points to be remembered regarding this class of operations:—

(1.) The slight constitutional disturbance in operations on the feet.

(2.) The large amount of bone which could be removed, and the very serviceable foot which could be left.

(3.) It seemed unnecessary in operating on the foot to pay any attention to articular surfaces.

DR. J. C. WARREN spoke of a case somewhat similar, operated on by Dr. Porter, with a very satisfactory result. It seemed to the speaker that this operation would be of great value in cases where, from one cause or another, mechanical treatment could not be carried out. Dr. Warren insisted on the point mentioned by Dr. Bradford, of carrying bandage above and below the two proximal joints to secure immobility of any one joint.

In reply to a question by Dr. W. S. Bigelow, as to whether the tarsus was regarded as a whole, DR. BRADFORD replied that the ankle-joint only was respected. The German surgeons did not do even this. This operation had been done by Dr. Reed, of New York, for equinus and those forms of club-foot due to ankylosis of the small bones.

DR. CAROT asked if it made any difference in the result whether the tendons on the anterior aspect of the foot were cut or not.

DR. BRADFORD said it had not seemed to. Treatment had lasted about three and one half weeks.

DR. J. C. WARREN showed some modifications of his apparatus for exerting pressure on long-standing irreducible hernia, consisting principally in the adaptation of a hard or soft rubber collar to the tumor so as to form a pedicle, allowing the requisite amount of pressure to be used without permitting the hernia

to escape laterally. He reported two cases, one of five and one of two years' standing, reduced by the aid of this apparatus. Reduction was effected in the former case in six weeks, in the latter in ten days.

ANTISEPTIC MANAGEMENT OF WOUNDS.

DR. W. S. BIGELOW called attention to a recent pamphlet, by Francis M. Caird, M. B., entitled, *Hints on the Antiseptic Management of Wounds*,¹ which gives concise directions for the application of Lister's method to operation and dressings. The book is scientific, practical, and thorough, and could be studied with especial advantage by the assistants and others on whom the thoroughness of the preparations for operations, which constitutes half the battle, depends. Every antiseptic operation ought to be carried out with as careful attention to the small details as if it were an experiment in spontaneous generation. Neglect of a single point, though seemingly trivial, imperils the result, and renders the other precautions useless. It is mainly on the assistants that the success of the antiseptic measures depends. It is impossible for a surgeon whose attention is fatigued by a long or difficult operation to have his eyes everywhere, and watch at the same time spray and sponges, towels and instruments. Yet a single wipe with an imperfectly disinfected sponge, for example, is as sure a maneuver as could be devised to invalidate the effect of every other precaution. This is one of the most common sources of trouble. Sponges are imperfectly disinfected beforehand, and left exposed during an operation in a way which courts failure. Wetting with carbolic solution just beforehand is wholly insufficient. A sponge containing dry germs is an exceedingly difficult thing to disinfect.

Some recent experiments of my own have made it apparent that the essential element in the devitalization of dry germ spores is *time*. An adult microbium is a very delicate and sensitive organism. A slight change in the temperature or the reaction of the nutritive fluid, or of the supply of nutrition, will determine the prompt destruction of many species. But between the growing organism and the dry spore there is a difference in sensitiveness analogous to that between a flower and a dry seed. A frost or a high temperature is promptly fatal to the former, while the latter will bear a good deal of baking or freezing without losing its power of germination, while its resistant outer envelope will withstand the action of many chemical reagents whose effect, if introduced in the sap of the plant, would be at once destructive. So with the microbia. It is from the dry germs of the organisms that danger is to be feared, and against them that precautions should be directed. Now, suppose a sponge, ordinarily clean, to be washed with common water, and put aside till wanted. Pasteur has shown that any water but spring water, collected before contact with the air, is filled with organisms and germs. With these the sponge is filled by the very washing which is meant to clean it. As it dries the germs remain as they are, and of the organisms, some die, and some which are ready to go to seed disappear and leave their germs behind. It would be hard to find a more difficult object to disinfect than a sponge in this state, and yet a more or less imperfect wetting with a five to one hundred solution before use is sometimes expected to accomplish the result. In reality the sponges should

be soaked for days in carbolic solution, and only taken out just before they are wanted. They should be stacked in a clean basin, and kept covered with a towel wet with carbolic, and never actually used for more than a minute before being replaced.

Similar precautions should be taken with instruments. The real safety in these is that they are habitually kept clean, and the germs do not adhere readily to the dry, polished surfaces. But the teeth of some forms of forceps are very hard to clean, and these as well as any other rough surfaces should receive special attention. The moment instruments are wet, however, any germ which touches them sticks, and this should be guarded against by keeping them completely covered by five to one hundred solution whenever laid down. Laying them on a wet cloth is utterly useless.

Sutures should be kept stuck in the under surface of the cork of a wide-mouthed bottle containing carbolized oil, and never in the assistant's coat.

Such details are often omitted or neglected from carelessness or routine, but they are among the essentials, without which an operation cannot be said to be thoroughly antiseptic. It may be said that many cases end successfully without them; so they do without any antiseptics whatever. But as the percentage of failure is smaller with antiseptics than without, so it is smaller with thorough antiseptic precautions than with half-way measures.

DR. A. T. CABOT asked about the use of a solution of carbolic in ether for preparing dressings.

DR. BIGELOW said that the difficulty is rapid evaporation. If the dressings were renewed often enough it might work. He had never tried it on wounds, but often used it in laboratory work for stopping flasks, etc., for which it is wholly unreliable.

DR. BRADFORD asked about disinfection by heat of cotton dressings.

DR. BIGELOW said it had been often recommended by Pasteur. The trouble with Guérin's cotton-wool dressings is that he shuts all the germs inside. If the cotton be heated till it just begins to char, shown by its turning a faint cream color, then all the germs it contains are also slightly charred, and, of course, dead beyond the possibility of resuscitation. Cotton-batting in rolls, in large, wide-mouthed jars, and with a few thicknesses of paper tied over the neck by a string, may be conveniently charred in this way in an oven, and will keep for some time if the cover is not disturbed. If the cotton be charred too much it becomes brittle and useless.

DR. MARCY spoke of his way of preparing dressings, and promised to show some at a future meeting.

Recent Literature.

A Manual of Ophthalmoscopy for the Use of Students. By DR. DAGUENET. Translated by C. S. Jeaffreson, F. R. C. S. E., etc. Philadelphia: Presley Blakiston. 1880.

The author's "object has been to condense, in as small a number of pages as possible, all that it is necessary to know to study with benefit diseases of the eye."

The arrangement of the subject-matter is, in general, good, but, except as to condensation, the author has fallen much short of the goal he attempted to reach.

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 8, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE CASE OF PRESIDENT GARFIELD.

SINCE immediately after the occurrence of the shooting of the President we have, as a weekly publication, and wisely, we think, refrained until now from comment upon the medical aspects of the case.

The hourly phases of this momentous illness have been made public, with all their details, as those of no other case of medicine or surgery ever were before. That the methods of their presentation have not always been satisfactory, even to those who "read between the lines," is made apparent by the fact that to the daily dispatch of "Blaine to Lowell," rather than to the "official bulletin," every eye has turned for reliable information of the President's condition. A lenient judgment must, however, be invoked for physicians who have borne the task of an attendance, the trying nature of which can be easily understood; and we ought, perhaps, to congratulate ourselves that no change has taken place in the *personnel* of the President's medical staff, in view of the possibilities which such a step might have involved.

It is an easy matter to speculate upon what would have happened if the assassination of President Garfield had occurred in New York, or Philadelphia, or Boston. It is in vain to wish that Dr. Agnew's surgical experience could have guided the treatment from the very outset; but it is none the less a fact that the President's case was one which called for the best skill of surgeons familiar with the daily practice of surgery, and proficient in all subjects pertaining to modern surgical pathology and therapeutics. It may be a question whether the encouraging hope that all was going on well was not a better sentiment to foster than one which would have revealed to an absorbed and expectant public, for example, the full and fateful meaning of the parotid inflammation, which every practiced surgeon realized as soon as its existence was made known. It may have been more politic to state that the "giving out" of the stomach was due to a dyspepsia which a soldier's and statesman's campaigns had occasioned, rather than that its true cause was the increasing exhaustion of blood-poisoning; but the one great "might have been" most to be wished is that, in so prominent and conspicuous a case, there should have been nothing said or done to impair the public's faith in the science of medicine as practiced by the profession, at the present time, in a country where its position has, in these latter days, acquired so great a prestige in the estimation of the whole world.

The suggestion has been made that the President's welfare would have been promoted by his earlier removal from Washington. In looking back we can now see that this could have been done, possibly with advantage, during some periods of the case; but the expectation of improvement, or the occurrence of imperfectly appreciated "relapses," must nevertheless have justified its repeated postponement. So far as we are aware, however, there has been no reason to suspect the malign influence of "malaria," either in that form which might be due to the location of the White House, or that modern variety to which the term is popularly applied, and which means the emanations from drains and soil-pipes, as having had any *direct* detrimental effect upon the President's condition.

The extent and perfection to which antiseptic measures have, or have not, been adopted calls for this much of comment, namely, — that perfectly antiseptic dressings and methods must have been very difficult to maintain in the treatment of such a wound as the President's; and, if the details in this respect have not satisfied the ultra disciples of Listerism, the attending physicians are entitled to what vindication they can find in the verdict of the recent International Congress, "that antiseptic treatment only answers one of the requirements of wound treatment; and that he only is a scientific surgeon who enlarges his views and practice to embrace them all."

FIRST ANNUAL REPORT OF THE NEW YORK STATE BOARD OF HEALTH.

ALTHOUGH submitted to the Governor of the State some months since, the above report has only recently been published in permanent form. It embraces the period from the organization of the Board on the 29th of May, 1880, to the first of the following December, and the amount of work accomplished by it during this first six months of its existence, as set forth therein, certainly goes to show that there was abundant need for the establishment of such an organization in the State. After some notice of the organization of the Board and the rules under which it is managed, the report takes up the subject of the public health laws, and points out the necessity for sanitary regulations for every town and village on the ground that there are sources of peril from various diseases and from causes of evil that require something more than individual efforts to secure even personal and domestic health, and much more to protect the public health. In view of the importance of this subject the Board has had prepared a compendium of the laws relating to public health and a brief outline of model sanitary ordinances, regulations, and orders adapted to the use of local boards of health in the State. Then follows a statement of the efforts of the Board to secure a complete registration of deaths, births, and marriages throughout the State, and a more efficient discharge of their duties by local boards of health.

The subject of preventable and prevalent diseases is next taken up, and the necessity of a suitable system for the observation and registry of disease pointed

out. The fact that twenty-five per cent. of all the mortality in the State is caused by only five of the diseases which destroy life, and that fully one third of the total sickness and mortality in the State is known to be preventable, is regarded as an ample reason for making a systematic study and registration of such diseases; and this duty, it is stated, has been satisfactorily commenced by the Board. Small-pox is the first infectious disease spoken of, and a brief notice is given of its occurrence in Troy and some of the surrounding villages and towns. The record of an outbreak of the disease among a factory population in West Troy very completely illustrates how recklessly the contagion is apt to be spread among the common people, and how promptly great employers of such people may take action which shall stamp out such an epidemic. Eighty persons were present at a masquerade party, and after several hours, when the company sat down to supper unmasked, it was discovered that one young woman had varioloid eruption on her face; but, instead of at once dispersing, the company continued their revelry until morning. The result of this wanton and culpable exposure was that twenty-two of the eighty individuals were attacked with varioloid or variola. As these cases all occurred in families of employees of a certain firm of manufacturers of woollen goods, the firm at once closed their mills and ordered all persons employed by them, in whatever capacity, to be vaccinated; enforcing the order by insisting that no individual should continue in their employment without presenting a certificate from a physician showing that they had been vaccinated, even though they might have had small-pox itself. The same emphatic orders also extended to the most thorough purification and disinfection of all dwellings in the place, and the consequence was that the outbreak was suddenly and completely terminated. Twenty-two cases resulted from exposure in the dance-hall, and eleven persons contracted the disease from exposure to these cases; while only one case occurred outside of the families thus exposed. Five of the whole number of cases were very severe, but none of them proved fatal.

In six widely separated regions of the State the Board was called to advise in regard to the prevalence and suppression of diphtheria. Among these were Geneva and its vicinity, where, among a population of seven thousand inhabitants, eighty deaths occurred from it in a period of fifteen months; the scattered forest townships of Arietta and Northville, in Hamilton and Fulton counties, respectively; and Otsego County, where, from a mild case in a farmhouse, situated upon a high hill, there occurred a series of malignant and fatal cases. The connection of a single tenement with a line of direct repropagation, traced nearly a hundred miles, and a significant instance reported from Middlefield, Otsego County, as traced back to a tenement in the village of Amsterdam, aptly illustrated the propriety of the measures for separation of the sick, and thorough disinfection, recommended by the Board in all cases of diphtheria.

Outbreaks of dysentery occurred in some of the villages of Long Island during the summer and autumn, and the subsequent investigations undertaken under the supervision of the Board left no doubt that the trouble originated in the contamination of the wells from privies, cess-pools, and other sources of defilement.

The reports and various complaints concerning malaria and the local sources of miasmatic disease outnumbered all others received at the office of the Board; and the most obvious fact derived from them was that drainage and sewerage for health do not yet appear to be the first object which local authorities have in view in their public works and the rules and regulations they enforce concerning them, whether in cities, villages, or the rural districts. The action advised or taken for relief and prevention in the instances referred to in the report unfortunately proved that the existing laws relating to general drainage of wet lands, etc., in the State were practically inoperative, and, further, that wherever they have been put into operation they have been the occasion for errors and abuses which the legislature did not foresee. Therefore, although the law creating the State Board of Health provides, in one of its sections, a mode of summary procedure to secure the protection of health and life in urgent cases, where nuisances are menacing the people, there seems to be great need of an improvement in the general laws relating to drainage and sewerage.

In regard to the purity of water supplies for domestic use, it is shown that the want of adequate laws for preventing the pollution of streams, wells, and other sources of supply is equaled only by the general neglect on the part of citizens of the duty to avoid the use of sanitarily impure and defiled water. The subject of providing pure supplies and of maintaining necessary local regulations to prevent the sources of defilement, it is stated, is now under discussion in various parts of the State, and is receiving the special attention of the Board and of the local authorities with whom it is in correspondence, and the Board has now issued to the latter a proposed form of sanitary regulations in regard to the matter. In the various reports and statements appended to the general report of the Board it is believed that there is abundant evidence that the local sanitary officers in different parts of the State are already coöperating with the State Board in a cordial and useful way. In conclusion it is stated that the work of the Board, as at present organized, has reached a point which will insure constant investigation and care of local causes of miasmatic diseases, of the interests of health and life as they are affected by water supplies, of safeguards against poisons and adulterations, of the danger from fluids used in common lighting, and of the sanitary wants of public institutions and places of assemblage, while, by the general registration of vital statistics, the dissemination and practical application of sanitary knowledge, and the maintenance of its central office in a state of complete readiness and efficiency, the Board must endeavor to extend its coöperation, and

offer the most useful information and counsel whenever local sanitary officers or the people of any community seek such aid in preserving life and health.

(To be concluded.)

MEDICAL NOTES.

NEW YORK.

—The sea-side nursery of St. John's Guild, recently opened at Cedar Grove, near New Dorp, Staten Island, is designed to be a model institution of its kind. It is a wooden structure, of yellow pine, having a frontage on the water (from which it is distant about thirty feet) of six hundred feet, and when entirely completed will consist of a central building and two wings. One of the wings is finished, but the other will not be erected till next summer. Special attention has been paid to the ventilation and drainage, and the closets are in a small, separate wing connected with the main building. All around the house there are verandas, some of which will at all times be in the shade. The Guild owns ten acres in the rear of the nursery, and the most of the land is covered by a fine cedar grove, which, it is believed, will add no little to the salubrity of the location. This institution is designed not to take the place of the floating hospital, but to supplement the work hitherto carried on by its agency. It frequently happens that children when seriously ill, after spending a day on the water on one of the excursions (although greatly benefited for the time being) are reduced to their previous condition after a single night spent in the unwholesome atmosphere of the tenement-house. Hence to secure permanent benefit in these worst cases taken upon the excursions a certain number of the children will be received into the nursery for as long a period as the circumstances in each case may require. The cost of endowing a bed in the institution is one hundred dollars, and the maintenance of quite a number has already thus been permanently secured.

—During the week ending August 14th the public baths were used by 286,821 persons, of whom 97,493 were females.

—A lodging-house in Thompson Street has been ordered to be vacated by the Board of Health, on account of its bad sanitary record. This is one of the buildings in which typhus fever appeared early in the spring, and from April 8th to July 21st there were removed from it twenty-two unmistakable cases of typhus, besides several in which the diagnosis was doubtful. The fever germs seem to have persistently adhered to the premises in spite of almost daily fumigations and frequent white washings and other efforts at purification. The emigration commissioners, having recently made an inspection of a number of the emigrant boarding-houses, have suspended the licenses of three of them on account of their unhealthy and filthy condition.

—A large new hospital (St. Mary's) to be under the direction of the sisters of charity of the diocese, is now being erected in Brooklyn. It is to cost six

hundred thousand dollars, and will accommodate one thousand patients, the care of which will be in the hands of a house staff of ten physicians and surgeons, with one hundred nurses. There will also be an outdoor department. The late Matthew Vassar in his will bequeathed eighty-five thousand dollars for the founding of a hospital to be known as "The Vassar Brothers Hospital" at Poughkeepsie, and in addition made this institution residuary legatee, an arrangement which will probably secure its endowment to the extent of two hundred and fifty thousand or three hundred thousand dollars.

Miscellany.

CRIME AND INSANITY.

MR. EDITOR, — In your issue of July 28, 1881, you reprint an article from the *Lancet*, entitled, Method in Madness, which refers to "the murderer of Mr. Gold" and "the man who attempted to assassinate the President of the United States," and you seem to indorse the same editorially. The closing sentences of the article read as follows: "The perpetrators of these heinous offences against common right and public safety may be more or less responsible for their acts, and, so far as they are concerned, more or less sane or insane. The measure of the morbid element in their individual cases will be the health or disease of the particular part or element of the brain from which the offense sprang. The ultimate judgment formed must be determined upon the basis of scientific tests to be applied to the action of the brain alleged to be the subject of partial or incipient disease. There is nothing in the facts, as they stand, to supply the materials for a judgment. Precise scientific inquiry can alone solve the enigma each case presents."

If this is written (and indorsed) simply from a metaphysical point of view, I have nothing to say, but if it is intended as a preliminary argument, I desire to take issue fairly and squarely with the writer and indorser.

What is the underlying principle of our modern penal code? Is it retaliatory, vengeful? Is an eye exacted for an eye, or a tooth for a tooth? By no means. When we hang a man it is with the intention of warning all other men not to commit so terrible a crime. When we put a man in prison it is with the hope that his discipline may prove reformatory.

But of late years a strange sentimentality has sprung up on this matter. A murderer has become a subject of especial interest. The life that he has extinguished is not considered, it is passed, gone, but *this* life, which is in such deadly peril is to be soothed (with rich viands), sweetened (with beautiful flowers), and prayed with till, by some hook or crook,—an *alibi* or the insanity dodge,—it may be rescued from the vale of death, and brought out into the sunshine of acquittal and—oblivion; and it is marvelous how simply and sweetly good, conscientious, pious people will lend themselves to a more or less open fraud to "save this brand from the burning."

The writer in the *Lancet* seems to think that "the materials for a judgment," in the case of these two criminals "must be determined up on the basis of sci-

entific tests to be applied to the action of the brain alleged to be the subject of partial or incipient disease." In this case no jury could ever be found—not even of psychologists—to decide upon the insanity nor even the sanity of any man. It has often been said that no "genius" was sane, because his mind was not well balanced, that it over-developed one quality at the expense of others; and, *à propos* of Guiteau, an eminent physician of New York is stated to have said that "no man who did not take his three square meals a day could be considered sane."

But most people, in and out of the profession, — psychologists and sentimental philanthropists excepted, — expect the laws to protect them from criminal assaults, and they will be as strongly inclined to believe that the common law is good enough for men who exhibit such very homeopathic conditions of insanity as the miscreants under consideration, and not care to "measure the morbid element in their individual cases" so fine as to defraud the ends of *real justice*. A. R. B.

BERKELEY, CALIFORNIA.

LONDON LETTER.

LONDON, August 23, 1881.

THE AMERICAN EDITION OF HOLMES' SURGERY; TORSION OF ARTERIES AT GUY'S HOSPITAL; MOORFIELD'S OPHTHALMIC HOSPITAL; CATARACT OPERATIONS, ETC.

MR. EDITOR, — Two or three things may interest you.

Did I tell you how indignant my friend Mr. Holmes is at the prospective issue of an American edition of his *System of Surgery*? He says that the first intimation he had of it was the advertisement in the *American Journal of Medical Sciences*. He is very emphatic in his denunciation of the project. He says there can be no excuse on the ground of the necessity of a modernized edition because he is busy editing a revised issue himself. He says that not only was he never notified by Mr. Lea, the publisher, or any one else, of any such intention, but that one of the gentlemen who is writing up one of the most important subjects had the ———? to write him asking his opinion upon certain points connected therewith, never alluding to the contemplated use of his answer. "I am sure," he said, "no one could be found in London who would do such a thing."

It is very unfortunate that there is not some proper adjustment of the international copyright interests.

Those of your readers who have not seen the Guy's Hospital Museum recently are not aware of the perfection in quality and detail of the *life-like* wax preparations. Every form of skin disease, acute and chronic, in every stage and variety, every kind of morbid growth, both before and in section after removal, either ante or post mortem, are shown, and so accurately that it requires very careful inspection to determine the fact that they are artificial. It is a most fascinating field for study, and an excellent place for an experienced practitioner to train himself in diagnosis by inspection.

At Guy's all the surgeons use torsion to the exclusion of the ligature, except sometimes in very small vessels wherein it is difficult to isolate the vessel from muscular fibres. They give a very large statistical

showing in its favor. I have seen every kind of amputation there except of the hip-joint, and never a ligature applied to a large vessel. They use no transverse forceps, but seizing the cut end of the vessel with strong forceps twist it until it is felt to "give way," that is, the two inner coats break. I have often seen six and sometimes ten complete turns given to the femoral artery. Mr. Bryant said, "Doctor, theoretically the twisted end ought to slough off, but *practically it never does*." We have to talk to our students about secondary hæmorrhage, but we do not show it to them." Mr. Lucas told me that for a long time they have ceased to dread or look for secondary hæmorrhage.

I saw Mr. Bryant perform excision of the head of the femur in a peculiar case. It was a case of traumatism in a child of four years, where there had been pain, tenderness, inguinal swelling, with *abduction* and *eversion* of the limb, and a sinus on the anterior aspect of the thigh at the middle. Child emaciated and feeble, but under ether the motions, which were free, developed *no crepitus*, nor was there any shortening, but, just as he predicted, the head was found carious rolling in a mass of granulations sprouting from a carious acetabulum, a perforation in which communicated with a pelvic abscess.

I have been at Moorfield's for a few days constantly, and there found my compatriot, Dr. Fox, of Philadelphia, a pupil of Professor Gross, as house surgeon. He has, like all the rest, been exceedingly kind. The greatest advances in ophthalmology just now are connected with refraction, especially in retinoscopy and keratascopy. Now we can determine the various affections of myopia, hypermetropia, astigmatism, etc., with the ophthalmoscope, and also ascertain the degree of corrective power. The advantage in case of children is obvious. Dr. Morton, of the hospital, has just published a valuable little monograph on the subject.

They generally make, in London, the modified linear extraction for cataract, making a small iridectomy upward, dividing the capsule by crucial incision, and after making the flap — they do not curve the last of it forward — remove the fixation forceps, and *do all the rest without supporting the globe*. You can imagine how much the operation is delayed and the operator embarrassed where the patient is compelled to keep the eye in position. In the same operation I have seen the operator have to make six or eight attempts both for seizing the iris and extracting the lens, because the poor patient could not keep the organ still, and hear him or her told, "You will lose your eye if you don't hold it still, and it will be your own fault." I have too often seen the lens driven backward, and vitreous humor escape, and a long and tedious search before extraction from lack of fixation. After a careful observation of results in a large number of cases, I have seen nothing, in uncomplicated cases, that equals a small corneal flap, base of incision close to the sclerotic, *curving it forward in the last third of its extent* about twenty-five degrees, and *incising the capsule along and just in front of the upper border of the lens* — the pupil being well dilated. If, as almost never happens when the incision is thus curved, the iris inclines to protrude at all, snip it off, otherwise leave the normal pupil. *Experientia docet*.

Sincerely yours,

WM. WARREN GREENE.

Deaths reported 3414; 1828 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1347; diarrhoeal diseases 839, consumption 374, diphtheria and croup 146, lung diseases 111, typhoid fever 102, malarial fevers 61, scarlet fever 55, small-pox 42, whooping-cough 41, cerebro-spinal meningitis 27, measles 16, erysipelas eight, puerperal fever six, typhus fever four. From *malarial fevers*, St. Louis 15, New York 14, New Orleans 10, District of Columbia eight, Brooklyn six, Baltimore three, Chicago and Buffalo two, Philadelphia one. From *scarlet fever*, New York 24, Brooklyn and Pittsburgh five, Philadelphia four, St. Louis and Baltimore three, Chicago, Boston and Buffalo two, New Orleans, Milwaukee, Lowell, Fall River, and Spencer one. From *small-pox*, Chicago 20, Philadelphia 10, New York six, Pittsburgh five, Brooklyn one. From *whooping-cough*, New York nine, Baltimore six, Chicago and St. Louis five, Brooklyn four, Providence three, Cincinnati and Buffalo two, Philadelphia, Boston, Fall River, Quincy, and Beverly, one. From *cerebro-spinal meningitis*, Chicago 10, New York six, Philadelphia four, Fall River two, Cincinnati, New Orleans, Buffalo, Lynn, and Taunton one. From *measles*, New York six, Pittsburgh three, Baltimore two, Philadelphia, Brooklyn, Chicago, Buffalo, and Providence one. From *erysipelas*, Brooklyn and Chicago two, New York, Boston, Baltimore, and Taunton one. From *puerperal fever*, Philadelphia, Brooklyn, Chicago, St. Louis, Baltimore, and New Orleans one. From *typhus fever*, New York four.

Five cases of small-pox were reported in Brooklyn, 57 in Chicago, and 44 in Pittsburgh; diphtheria 16, scarlet fever three, in Boston; diphtheria seven, scarlet fever five, in Milwaukee.

In 10 cities and towns in Massachusetts, with a population of 1,010,124 (population of the State 1,783,086), the total death-rate for the week was 28.67 against 27.58 and 29.16 for the previous two weeks.

For the weeks ending July 23d and July 30th in 149 German cities and towns, with estimated populations of 7,556,846

and 7,699,657, the death-rates were 35 and 31.2. Deaths reported in the respective weeks 5182 and 4717; under five 3280 and 3072; diarrhoeal diseases 647, 563; pulmonary consumption 463, 435; acute diseases of the respiratory organs 263, 199; scarlet fever 100, 86; diphtheria and croup 89, 105; typhoid fever 56, 55; whooping-cough 42, 42; measles and *rötheln* 46, 34; puerperal fever 15, 13; typhus fever one, seven; small-pox four, one. The death-rates in the respective weeks ranged from 16.7 in Metz to 54 in Breslau; and from 14.6 in Bremen to 45.9 in Posen; Königsberg 25.5, 31; Breslau, 44.6; Munich 31.9, 40; Dresden 32.4, 35.2; Berlin 54, 44.5; Leipzig 30.9, 31.6; Hamburg 33.4, 27.1; Hanover —, 24.1; Bremen 26; Cologne 32.7, 32; Frankfort 22.7, 18.6; Strasburg 36.8, 33.8.

For the weeks ending July 30th and August 6th in the 20 English cities, with an estimated population of 7,608,775, the death-rates were 25.2 and 22.9 respectively. Deaths reported 3673 and 3342; diarrhoea 776, 533; acute diseases of the respiratory organs (London) 156, 165; scarlet fever 106, 95; measles 104, 99; whooping-cough 79, 63; small-pox (London 39, 38) 43, 41; fever 26, 38; diphtheria 23, 16. The death-rates ranged from 12.4 in Wolverhampton to 36.9 in Leicester, and 9.7 in Plymouth to 30.1 in Leicester in the respective weeks; Bristol 17.4, 17.9; Sheffield 17.7, 20.1; Manchester 22.5, 22; Birmingham 23.9, 19.1; London 27.2, 23.4; Liverpool 29, 27.3; Leeds 29.2, 22.5. In Edinburgh 14.1, 16.2; Glasgow 19.4, 23.6; Dublin 17.5, 19.4.

In the 21 chief towns of Switzerland, for the weeks ending July 30th and August 6th, population 479,934, there were respectively 49 and 77 deaths from diarrhoeal diseases; acute diseases of the respiratory organs 12, 15; diphtheria and croup eight, six; whooping-cough six, —; typhoid fever five, four; measles —, two; puerperal fever —, one. The death-rates for the respective weeks were: Geneva 12.9, 24.3; Zurich 29.1, 23; Basle 26.8, 23; Berne 25.8, 34.1.

The meteorological record for the week in Boston was as follows: —

Deaths reported 3095 (no returns from New Orleans or Charleston): 1640 under five years of age: principal "z-motic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 1214, diarrhœal diseases 694, consumption 338, diphtheria and croup 159, lung diseases 128, typhoid fever 110, small-pox 61, scarlet fever 56, malarial fevers 54, whooping-cough 46, cerebro-spinal meningitis 14, measles 10, puerperal fever six, erysipelas three, typhus fever one. From small-pox, Chicago 28, Pittsburgh 17, Philadelphia 10, New York six. From scarlet fever, New York

20, Brooklyn and Pittsburgh nine, Philadelphia seven, Chicago, Baltimore, and Buffalo two, Providence, New Haven, Worcester, Fall River, and Westborough one. From malarial fevers, New York and St. Louis 15, Baltimore eight, District of Columbia seven, Brooklyn and Chicago three, Cincinnati, New Haven, and Nashville one. From whooping-cough, Brooklyn 11, Philadelphia eight, Chicago seven, New York five, Boston and Cincinnati four, St. Louis and Buffalo two, Baltimore, Pittsburgh, and Providence one. From cerebro-spinal meningitis, Chicago and St. Louis two, New York, Philadelphia, Cincin-

ti, Lowell, Worcester, Lawrence, Lynn, Chelsea, Attleborough, and Westborough one. From *measles*, New York four, Chicago three, Brooklyn two, Pittsburgh one. From *puerperal fever*, Chicago two, New York, District of Columbia, New Haven, and New Bedford one. From *corysipelus*, Brooklyn, St. Louis, and Pittsburgh one. From *typhus fever*, New York one.

Seven cases of small-pox were reported in Brooklyn, 25 in Chicago, 38 in Pittsburgh; diphtheria 11, scarlet fever four, in Boston; diphtheria 15, scarlet fever three, in Milwaukee. Dysentery is prevalent in Buffalo.

In 11 cities and towns of Massachusetts, with a population of 1,079,343 (population of the State 1,783,986), the total death-rate for the week was 22.85 against 28.67 and 27.58 for the previous two weeks.

For the week ending August 6th in 149 German cities and towns, with estimated populations of 7,794,129, the death-rate was 30.8. Deaths reported 4612; under five 3822; diarrhoeal diseases 530, pulmonary consumption 487, acute diseases of the respiratory organs 210, scarlet fever 88, diphtheria and croup 88, typhoid fever 66, whooping-cough 40, measles and röteln 20, typhus fever (Königsberg, Stettin, Berlin two) 4, small-pox (Königsberg, Aachen, Stettin) three. The death-rates ranged

from 9.8 in Metz to 48.1 in Chemnitz; Königsberg 31.6; Breslau 45.4; Munich 34.6; Dresden 34.5; Berlin 37.8; Leipzig 30.9; Hamburg 28.6; Hannover 22; Bremen 22.4; Cologno 31.8; Frankfurt 23.4.

For the week ending August 13th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 21.7. Deaths reported 3167; diarrhoea 483, acute diseases of the respiratory organs (London) 148, scarlet fever 110, measles 87, whooping-cough 61, fever 42, small-pox (London) 29, diphtheria 19. The death-rates ranged from 14.7 in Bradford to 36.9 in Leicester; Manchester 18.7; Sheffield 19.5; Bristol 20.2; Birmingham 21; London 21.5; Liverpool 24.3; Leeds 26.2. In Edinburgh 17.1; Glasgow 20.9; Dublin 22.2.

In the 21 chief towns of Switzerland, for the week ending August 13th, population 479,934, there were 79 deaths from diarrhoeal diseases; acute diseases of the respiratory organs and typhoid fever each 10, diphtheria and croup seven, whooping-cough five, puerperal fever three, measles two. The death-rates were: Geneva 21.8; Zurich 27.8; Basle 27.6; Berne 31.6; St. Imier 87.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 27, 1881, TO SEPTEMBER 2, 1881.

BYRNE, CHARLES C., major and surgeon. Relieved from duty at Angel Island, Cal., and assigned to duty as post surgeon at Benicia Arsenal and attending surgeon at Benicia Barracks, Cal. S. O. 142, Military Division of the Pacific and Department of California, August 23, 1881.

COLES, ELLIOT, captain and assistant surgeon. Granted leave of absence for one month, to take effect when relieved by a medical officer, with permission to apply for three months' extension. S. O. 97, Department of Arizona, August 23, 1881.

KING, WILLIAM H., captain and assistant surgeon. To ac-

company Battery I, Third Battery, to Yorktown, Va., and remain with it until further orders. S. O. 153, Department of the East, August 31, 1881.

ADAIR, GEORGE W., captain and assistant surgeon. Granted leave of absence for two months. S. O. 196, A. G. O., August 26, 1881.

STRONG, N., first lieutenant and assistant surgeon. To proceed to Park City, Utah, report for temporary duty to commanding officer of the troops en route to Fort Thornburgh, Utah, and remain on such duty until arrival of Captain W. C. Shannon, Assistant Surgeon United States Army. S. O. 84, Department of the Platte, August 29, 1881.

ARTHUR, W. H., first lieutenant and assistant surgeon. Granted leave of absence for one month, to take effect from the date of return of Surgeon Forwood to Fort Omaha. S. O. 82, Department of the Platte, August 24, 1881.

Original Articles.

RESECTION OF THE TARSUS IN SEVERE CASES OF CONGENITAL CLUB-FOOT.

BY E. H. BRADFORD, M. D.

DR. LITTLE, of London, was the first to suggest removal of a portion of the tarsus (the cuboid bone) as a means of shortening the treatment in "inveterate varus."¹ This was done, in 1854, by Mr. Solly, of St. Thomas Hospital at the recommendation of Dr. Little. The result was less successful than was anticipated, owing, apparently, to the difficulty encountered in maintaining the corrected position of the foot by means of the appliances used. The patient recovered from the operation.²

Mr. Lund³ removed the astragalus in a similar case with success. The details have, however, not been given with sufficient accuracy to justify a clear opinion as to the perfection of the cure.

Dr. Mason, of New York, was obliged to amputate in a case where he had unsuccessfully excised the astragalus⁴ and a portion of the external malleolus.

Verbelzi successfully dissected out the astragalus in a case of congenital club-foot in a child five and one half years old.⁵ The exact details I have been unable to find.

Mr. Lund showed before the London Clinical Society a case where he had successfully removed the astragali in double congenital talipes. The boy was able to walk about readily. The astragalus was excised (after an incision through the soft parts) by means of a gouge and a short curved hook, with a cutting edge on its concavity.

Mr. Thos. Smith and Prof. John Wood have also performed the operation successfully.⁶

Mr. Davy has operated in three cases by removing simply the cuboid bone, and in three cases by excising a wedge-shaped piece from the tarsal arch. Death from septicæmia occurred in one case. In the others recovery took place, and from the report the cases progressed favorably.⁷

Davies Colley operated by resection of the tarsal bones on a child twelve years old; ten days after the operation on the second foot, and twelve weeks after the first operation, the patient was able to walk about without any apparatus. Two months later, when re-examined (no apparatus having been worn in the interval), the foot was found in good position, the boy treading on the whole of the sole. The patient could walk, hop, and jump. Six months later he was able to walk eight miles.⁸

König,⁹ Rupperecht,¹⁰ Meusel,¹¹ report, respectively, three, five, and five operations of resection of the tarsus for severe club-foot. All are mentioned as successful with the exception of one under the care of König, where death occurred ten days after the opera-

tion. At the autopsy it was found that the patient had been suffering from ulcerative endocarditis, with valvular disease of the heart, and with pathological changes in the lungs.

Ried has removed in congenital club-foot in children the astragalus and a portion of the os calcis in one case, in a second a wedge-shaped portion of the tarsus, and in a third the astragalus alone. The results are reported to be entirely satisfactory. In two cases of acquired equinus in an adult with ankylosis of the tarsus, a wedge-shaped section was made by means of a key-hole saw (first boring through the bones) through the tibia and fibula and the astragalus. In four weeks the wound was healed, in three the patient was able to walk with crutches, and the ultimate result was said to be entirely satisfactory.¹²

West¹³ excised the astragalus, the scaphoid, and the cuboid bones in a patient, twenty-three years old, suffering from talipes equino-varus, gaining a good result in ten weeks.

Bryant¹⁴ and Schede successfully removed a wedge-shaped section from the tarsus, and the latter showed their patients before the VII. Congress of German Surgeons.¹⁵

Hueter,¹⁶ in an adult, resected the head of the astragalus and the scaphoid, and the result was a useful foot.

Dr. C. B. Porter¹⁷ operated upon a boy by excising a wedge-shaped portion of the tarsus, obtaining an excellent result.

In the two following cases the patients came under my care suffering from severe relapsed congenital equino-varus. In the first case the deformity was single, in the second double.

CASE I. Cora W., eleven years of age, an inmate of an orphan asylum, was sent to the Children's Hospital for treatment, with severe equino-varus; the patient walking upon the outer edge and dorsum of the foot.

Tenotomy and mechanical treatment were tried for a month with but slight benefit. On August 27th a wedge-shaped section of bone was removed from the tarsus. The operation was done under antiseptic precautions. The section was made with a metacarpal saw, and the fragments removed with dressing forceps. After the operation the wound was covered with an antiseptic gauze dressing, a cotton bandage was wound over the foot and leg, and then a plaster of Paris bandage applied. After this had hardened a fenestrum was cut; the gauze over the wound cut open, laid back on the plaster bandage and carbolized putty packed in at the edge of the fenestrum; an ordinary antiseptic gauze dressing was applied over the whole; no constitutional disturbance followed the operation; the temperature rose once to 101° F., but with this exception remained normal; the wound healed under the blood clot as occurs under a thorough antiseptic dressing; in five weeks the patient was able to walk about without a cane; she remained in the hospital for some time under observation and was discharged with the foot in nearly a normal position. Nine months later the patient was again examined. She had worn no appliance in the interval, the foot had shown no tendency to relapse, the child wore an ordinary boot, could stand on the toes of the

¹⁷ Unpublished case.

previously affected foot, but could not flex the foot beyond a right angle with the leg. The patient walked nearly on the whole of the sole of the foot, placing the heel well down at each step, as is shown by the accompanying tracing, taken by wetting the foot and allowing the patient to stand until the moistened impression was taken on the paper.

CASE II. R. F., boy thirteen years old, double congenital club foot, of aggravated type. The patient was only able to wear shoes made especially and walked on the dorsum and outer side of the foot.

The first foot was operated on November 9, 1881. By December 12th the boy was able to bear weight upon the limb; by January 19th the wound was entirely healed. January 9th the second operation was performed; on February 4th he was allowed to walk about both feet. The patient remained in the hospital until April 2d, under observation. At this time he walked a mile and used no apparatus or cane, wearing ordinary shoes. No sinus remained after either operation. The temperature rose after the first operation to 102° F. on the second day, but fell to normal the next day and remained so. After the second operation on the third day the temperature rose to 101° F., but fell after removing the drainage tube, which was stopped; no subsequent rise in temperature took place. Tenotomy was done in the second but not the first case and was of help in allowing the soft parts to stretch. Both feet were fixed after the operation in plaster-of-Paris bandages. The method recommended by Reeves of holding the foot during the application of the bandage was tried in the second but not in the first foot. This consists of pulling the tarsus in by means of a strip of bandage passed around the ankle and held by an assistant; the toes are held and forced by the hand of an assistant in an opposite direction, and this position is maintained until the plaster has become hard. After the second operation also the plaster-of-Paris bandage was applied

not only to the knee but above it. This was found to prevent the plaster shell from rolling around the leg and allowing the front of the foot to evert.

The correction of the position in the second foot was much more perfect than in the first, owing to the improvements in detail. In both, however, the boy was able to stand on the flat of the sole. There remained after recovery about thirty degrees of motion at the

ankle; the feet could be brought to a right angle but not flexed beyond that. The boy could stand on the flat of either foot or raise himself on his toes, but while standing on the heels could not raise the toes from the ground. The amount of bone removed in the three cases varied, a larger section was excised in the last than in either of the other cases. In all, the cuboid and one cuneiform were removed entirely and in addition a section made of the astragalus, os calcis, cuneiform scaphoid, and head of the fifth metatarsal.

Nos. 2 and 4 show the foot before, Nos. 1 and 3 after operation.

The section was most readily made with a chisel, and a vice for securing the heel, made by Dr. Fletcher Abbott (consisting of a joiner's clamp with a cup-shaped hollow cut out to fit the heel, and secured to the table

by a second clamp) was of great help in steadying the limb during the use of the chisel.

All the operations were performed and the wounds dressed strictly antiseptically.

That the operation be accepted generally by surgeons as a recognized method of treatment, it is essential that the deformity be thoroughly corrected and that no ill effects follow the surgical interference.

Antiseptic precautions offer the best safeguard, and it must be admitted that a study of the reported cases justifies the impression that the danger is not so great as has been supposed.

The results hitherto obtained have been such that a serviceable and nearly perfect foot is given in the place of a deformed one, in a relatively short time enabling the patient to walk on the flat of the sole without noticeable deformity, but there has not been the restoration of a foot absolutely normal in shape and in motion as have been gained by the method of tenotomy and gradual mechanical correction even in severe cases. This has only been done, however, by the expenditure of great care on the part of the surgeon and attendant, and after a very protracted treatment, facts which practically debar, to a great extent, from the benefit of treatment the pauper class: a class which furnishes the larger part of the contingent of severe relapsed club-foot.

OBSTETRIC AND GYNÆCOLOGICAL LITERATURE, 1876-1881.¹

ADDRESS ON OBSTETRICS AND DISEASES OF WOMEN.

JAMES R. CHADWICK, M. D., BOSTON, MASS.

INSTEAD of following the routine custom of presenting in this address the advances that have been made in the department of obstetrics and gynecology during the past year, I propose to ask your attention to a statistical consideration of the whole volume of literature upon this branch of medicine during the past five years. I shall present a quantitative analysis of this literature with reference to nationalities, and shall finally sketch the rise and fall of the interest evinced in certain special topics as shown by the number of separate publications and journal articles published in each successive year. These enumerations I am enabled to make by utilizing the annual Indices of the Gynecological and Obstetric Literature of all Countries, published under my supervision in the Transactions of the American Gynecological Society. The Index for the year 1876 only covers the last six months of the year, and is therefore of but limited utility. The Index for the year 1879 is in print, but is not yet published; that for 1880, though on cards and now in course of preparation for the printer, has nevertheless proved available for my purpose. The space of time covered by my review is, unfortunately, limited to five, or more strictly speaking, to four and a half, years, so that my sketches of the different topics can in no instance embrace more than a brief epoch in the life-history of any method of treatment, operation, or theory. Such a numerical analysis of current literature, if it could be made to cover a longer term of years, would, I am convinced, show some strange mutations in the popularity of certain topics, and would dampen the ardor of many authors who have sought to attain immortality by pro-

pounding new theories, devising new operations, and above all, by inventing new instruments. Of course the number of articles published upon a given new topic is not, in every instance, an accurate test of its merit. Many new ideas are of such nature as to appeal to a limited audience. A new therapeutic remedy or a new operation, on the other hand, is pretty sure to meet a warm reception. Its life history may then be outlined somewhat as follows: an article is written recounting the success obtained by its author in the treatment of a certain condition by a new operative method. Immediately it is tried by many practitioners, who hasten to publish their results, particularly if favorable, when they may expect to derive renown or practice from being early identified with the innovation. Articles multiply rapidly, the operation has been forced upon the attention of the whole profession; soon its charm of novelty wears off, and the number of papers would rapidly diminish were it not that the negative or unfavorable results obtained begin to be published; the true merits of the operation are gradually reached, and finally it is either adopted as part of the traditional store of operative procedures, or is renounced and forgotten. A familiar recent instance of this course of events is observable with regard to incision of the cervix uteri for dysmenorrhœa, advocated many years ago by Sir James Y. Simpson. This operation at once appealed to the mechanical instincts of the profession, was taken up with avidity, was advocated in all the medical journals of the world, was variously modified by different operators, each of whom sought by numerous papers to have his special method adopted; opponents soon raised their voices; the operation was shown conclusively not to be followed by the promised relief in many cases, and, moreover, to be fraught with some danger. To-day this operation is rapidly passing into oblivion. It is still performed in cases of extreme stenosis, but is recognized as inadequate to afford relief in the vast majority of cases for which it was formerly recommended. My table shows a progressive decrease in the number of papers on this subject during the past five years. A similar fate may safely be predicted for several operations now held in high esteem, such as the operation for laceration of the cervix uteri, Freund's method for the complete extirpation of the cancerous uterus, Porro's Cesarean section followed by excision of the uterus, etc.

OBSTETRIC AND GYNÆCOLOGICAL PERIODICALS.

Before passing to an analysis of the whole volume of literature, let me direct your attention for a few moments to the special periodicals, including journals and society transactions, devoted to this branch of medical science:—

¹ Read before the American Medical Association at its thirty-second meeting, held in Richmond, Va., May, 1881.

This table shows that the total number of periodicals has increased in the five years from thirteen to twenty-two, nearly sixty per cent.; that the American have increased one hundred per cent., the French fifty per cent., the German thirty per cent.; that Belgium, Italy, and Denmark have entered the lists with one periodical each; and that England and Spain have remained unchanged.

The twenty-two periodicals being published in 1880 are as follows:—

TITLES OF PERIODICALS DEVOTED TO OBSTETRICS AND GYNÆCOLOGICAL LITERATURE IN 1880.

Country.	First published.	Title of Periodical.
America.	1869	American Journal of Obstetrics and Diseases of Women and Children. Editor, Dr. P. F. Mundé. 8vo. Quarterly. New York.
	1869	Philadelphia Obstetrical Society. Transactions. Secretary, Dr. W. H. H. Githens. 8vo. Uncertain. Philadelphia.
	1873	Obstetrical Journal of Great Britain and Ireland, with an American Supplement. American Editor, Dr. J. V. Ingham. 8vo. Monthly. Philadelphia.
	1877	American Gynecological Society. Transactions. Secretary, Dr. J. R. Chadwick. 8vo. Yearly. Boston.
	1878	Obstetric Gazette. Editor, Dr. E. B. Stevens. 8vo. Monthly. Cincinnati, Ohio.
Great Britain and Ireland.	1879	Homœopathic Journal of Obstetrics and Diseases of Women and Children. Editor, Dr. H. Minton, of Brooklyn. 8vo. Quarterly. New York.
	1859	Obstetrical Society of London. Transactions. Hon. Secretaries, Dr. J. Williams and Dr. C. Godson. 8vo. Yearly. London.
	1868	Edinburgh Obstetrical Society. Transactions. Secretaries, C. E. Underhill, M. B., and C. Carmichael, M. D. 8vo. Yearly. Edinburgh.
	1873	Obstetrical Journal of Great Britain and Ireland, including Midwifery and the Diseases of Women and Children. ¹ Editor, Dr. A. L. Galatin. 8vo. Monthly. London.
	1872	Gazette Obstétricale. Rédacteur, Dr. L. E. Dupuy. 8vo. Fortnightly. Paris.
France.	1873	Journal des Sages-femmes. Rédacteur, H. Foutan. 4to. Fortnightly. Paris.
	1873	Archives de Tocologie, des Maladies des Femmes, et des Enfants nouveau-nés. Rédacteur, Dr. De Soyre. 8vo. Monthly. Paris.
	1873	Annales de Gynécologie (Maladies des Femmes, Accouchements). Rédacteur, Dr. A. Leblond. 8vo. Monthly. Paris.
	1879	Revue médico-chirurgicale des Maladies des Femmes. 8vo. Monthly. Paris.
	1880	L'Obstétrique. ² Rédacteur, Dr. A. Mattei. 8vo. Monthly. Paris.
Germany.	1870	Archiv für Gynäkologie. Rédacteurs, Dr. Crede and O. Spiegelberg. 8vo. Uncertain. Berlin.
	1877	Zeitschrift für Geburtshilfe und Gynäkologie. Rédacteurs, C. Schröder, H. Fasbender, A. Gussacrow, L. Mayer, in Berlin. 8vo. Uncertain. Stuttgart.
	1877	Centralblatt für Gynäkologie. Rédacteur, Dr. H. Feilberg, in Stuttgart, Dr. H. Frisch, in Halle, A. S. 8vo. Fortnightly. Leipzig.
	1877	Gynækologiske og obstetriske Meddelelser. Udgivne af F. Horwitz. 8vo. Half-yearly. Kjøbenhavn.
	1879	Annali di Ostetricia, ginecologia e pediatria. Editore, Dott. C. Alessandro, Università di Modena. 8vo. Monthly. Milano.
Spain	1875	Sociedad ginecologica Española. Anales. Secretario, Sr. D. A. R. Rubi y Pacheco. 8vo. Monthly. Madrid.

¹ Discontinued after vol. xii, No 12, December 30, 1880.

² Terminated on the death of the editor, 1881.

Belgium. 18

Journal d'Accouchements. Écho de la Maternité de Liège. Rédacteur, Dr. N. Charles. 4to. Fortnightly. Liège.

In 1876 was published the Zeitschrift für Geburtshilfe und Frauenkrankheiten. Rédacteurs, Dr. E. Martin and Dr. H. Fasbender, vol. i., 8vo, uncertain, Stuttgart, which was converted into the Zeitschrift für Geburtshilfe und Gynäkologie in 1877.

In 1879 was published by the New York Obstetrical Society, Transactions for the years 1876, 1877, and 1878. 8vo. Vol. I. Uncertain. New York. 1879.

The special periodicals may be regarded as one gauge of the degree of interest taken in this branch of medicine in the different countries.

Certain characteristics distinguished the publications of the different countries. For instance those of Germany contain more contributions to the science of medicine, whereas those of America contain more papers of a practical nature; those of France are more controversial, being more essentially the organs of separate cliques, etc.

OBSTETRIC AND GYNÆCOLOGICAL SOCIETIES.

Another means of estimating the relative prominence of this branch of medicine in different countries is an enumeration of the special societies.

NUMBER OF OBSTETRIC AND GYNÆCOLOGICAL SOCIETIES, 1876-1880.³

		Obstetrical and Gynecological Society of St. Louis. Secretary, Dr. George J. Engelmann. St. Louis Courier of Medicine.
		Cincinnati Obstetrical Society. Transactions. Secretary, E. B. Stevens, M. D., Cincinnati, Ohio. American Journal Obstetrics. New York.

³ In this list are included the general societies which have sections specially devoted to obstetrics and gynecology.

		San Francisco Obstetrical Society.
		New York Academy of Medicine. Obstetrical Section. New York Medical Record.
		Chicago Gynecological Society. Transactions. Chicago Medical Journal and Examiner.
Great Britain and Ireland.	1859	Obstetrical Society of London. Transactions. Hon. Secretaries, John Williams, M. D., and Clement Godson, M. D. Vol. XXI, 411 pp. Svo. Yearly. London. 1880. Also, Abstract in Obstetrical Journal of Great Britain. London.
		British Medical Association. Obstetric Section. Abstract of Proceedings. British Medical Journal.
	1868	Edinburgh Obstetrical Society. Transactions. Secretaries, C. E. Underhill, M. B., James Carmichael, M. D. Vol. V., Part 3. Svo. Edinburgh. 1880. Also, Abstract in Obstetrical Journal of Great Britain.
		Obstetrical Society of Dublin. Abstract of the Proceedings. Obstetrical Journal of Great Britain. London.
Germany.	1866	Versammlung deutscher Naturforscher und Aerzte in Cassel. Gynäkologische Section. Verhandlungen. XVI. Centralbl. f. Gynäk. Berlin. Also, Arch. f. Gynäk. Berlin. Also, American Journal Obstetrics. New York.
		Gesellschaft für Geburtshilfe und Gynäkologie in Berlin. See Ztschr. f. Geburtsh. u. Gynäk.
		Gesellschaft für Geburtshilfe in Leipzig. 1878-79. Mittheilungen. Arch. f. Gynäk. Berlin.
France.		Französischer Naturforscherversammlung. Sitzung zu Montpellier. Gynäkologische Section. Centralbl. f. Gynäk. Berlin.
Spain.		Sociedad ginecológica española. Anales Año de 1879. Secretario general, Sr. D. A. R. Rubi y Pacheco. Tomo V. Svo. Madrid. 1880.
Russia.		Allgemeines Verein St. Petersburger Aerzte. Gynäkologische Section. Verhandlungen. St. Petersb. med. Wehschr.

We see here at a glance how greatly America predominates in this list, containing as many societies as exist in the rest of the world. Too great significance must not, however, be attached to this fact, for one cause of this development of societies is purely geographical. In England it is possible for those who are

specially interested in gynecology and obstetrics to attend the meetings of the Obstetrical Society of London, as actually happens, whereas in America the distances to be traversed are so great as to render this impossible. As a result of these two extremes we find the English society has seven or eight hundred members, while the membership of the American societies ranges from twenty to fifty. The lack of any special society in France is striking, and unaccountable when contrasted with the large number (6) of special journals issued in that country.

OBSTETRIC AND GYNECOLOGICAL LITERATURE.

We now come to the consideration of the whole bulk of the special literature; it may best be appreciated by the aid of this table.

		Sep. Pub.	Articles.	Articles.	Total.
Last six months of 1876	..	91	= 1374	+ 753	= 2127
1877	..	194	= 2388	+ 1698	= 4086
1878	..	168	= 1320	+ 2203	= 3523
1879	..	265	= 2194	+ 2644	= 4838
1880	..	201	= 2410	+ 2770	= 5188

In this table I have resolved the separate publications into their equivalents in journal articles, reckoning an article at an assumed average length of ten pages, which is certainly above rather than below the average length of articles. The rate will, however, serve as a convenient basis for the reduction.

It will be noticed in the first place that the volume of this special literature is increasing at the rate of twenty-five per cent. a year. The volume of literature thus shown to be devoted yearly to a single branch of medicine is certainly appalling and fully justifies the urgent need for specialization of practice already in process of evolution. Even admitting that ninety per cent. of these writings merely reiterate facts in medicine already too familiar to gynecologists, yet there still remains an immense amount of reading incumbent upon one who would keep abreast with the advances in this, to say nothing of the collateral branches of medicine.

A still further analysis of these figures for one year (1880) discloses some interesting facts with reference to nationalities.

ANALYSIS OF THE LITERATURE OF THE YEAR 1880 BY NATIONALITIES.

Countries.	Obstetric.				Gynecological.				Total Obstetrical and Gynecological.		Total Books and Papers.

Portugal	-	-	-	-	-	-	1	1	-	1	1
Venezuela	-	-	-	-	1	2	-	2	-	2	2
Total	106	1263	1445	2708	96	1147	1313	2459	201	2770	5188

In the first place, France has issued the greatest volume of literature, equivalent to 1658 articles; America 1345; Germany, Great Britain, and Ireland 488. Analyzing these we have —

France, . . . obstetrical, 948; gynecological, 710 = 1658
America, . . . obstetrical, 624; gynecological, 721 = 1345
Germany, . . . obstetrical, 421; gynecological, 433 = 854
Grt. Brit. and Ire., obstetrical, 269; gynecological, 270 = 539

This predominant interest of France in obstetrics may be shown to be restricted to a moderate number of writers, for on analyzing the French contributions closely it appears that fifty-one separate publications (books, theses, etc.) were published during the year, which had been estimated as equivalent to 598 articles; deducting these from 948 we have remaining only 350 real journal articles. In America only nine books were issued, equivalent to 126 articles, leaving 498 articles. In Germany a similar process reduced the articles to 170, in England to 161.

Under gynecology similar reductions change the relations as follows: France 301 articles; America 359 articles; Germany 215 articles; Great Britain and Ireland 166.

The inferences from these figures may be summed up as follows: In America there is a much greater number of contributions on both general branches than in any other country. In France the whole volume of obstetric literature, nevertheless, exceeds that of America by one fifth, a curious discrepancy which may be attributed mainly to two factors: first, the publication of graduation theses, and second, the stimulus given to the professors to the writing of treatises from the rivalry engendered by the close propinquity of the fields of their labor; that this, by their being mostly inhabitants of Paris, and having charge of competing clinics. The cause of the small number of contributions from Germany is probably due to the fact that they emanate chiefly from university professors and instructors, whose chief motive is the desire for academic promotion, and whose writings are consequently, for the most part, records of extensive research or investigation and addressed mainly to the ministry of education; they are hence much longer, on the average, and require a longer time for their preparation. I am at a loss to explain the lack of interest displayed in England by these figures.

SPECIAL SUBJECTS IN OBSTETRICS AND GYNECOLOGY.

Carrying my analysis one step farther, I shall finally bid you scrutinize a table in which are given the number of articles upon certain definite topics in the successive years, and shall offer a few suggestions in explanation.

Under the general heading of Ovariectomy we see a marked increase from year to year. Under the sub-head of Ovariectomy there is a steady increase, while in the past two years there has been a steady decrease in the number of Cases of Ovariectomy; the cause must be apparent to all. Normal Ovariectomy, which was devised and first carried out by the genius and pluck of our countryman, Dr. Battey, has deservedly claimed more attention during the past three years than any other new operation, but during 1880 its volume of literature has been on the wane, its true value and limits of usefulness having been nearly defined.

TABLE OF SPECIAL TOPICS.

	Last half of 1876	1877	1878	1879	1880
Ovariectomy	4	30	36	45	158
Ovariectomy during pregnancy	—	3	2	—	—
Ovariectomy, vaginal	1	1	1	—	—
Ovariomy, antiseptic	—	—	14	25	20
Ovariectomy, double, cases of	—	—	—	12	5
Ovariectomy, cases of	45	92	143	126	76
Total	50	123	196	208	259
Ovariectomy, normal	—	3	19	108	32
Porro's operation, Cesarean section, with extirpation of the uterus	—	—	—	24	41
Albuminuria	8	5	7	4	33
Eclampsia	5	—	—	—	—
Puerperal convulsions	35	80	82	184	94
Total	48	85	89	188	127
Forceps	9	17	29	45	37
Hæmorrhage, post-partum	12	29	34	44	42
Hysteria	5	9	25	11	11
Hystero-neurosis	—	4	7	11	—
Hystero-epilepsy	—	—	9	21	6
Total	5	13	41	43	17
Intra-uterine injections	—	2	10	7	11
Abortion	22	16	46	39	32
Abortion, criminal	—	—	4	10	3
Total	22	16	50	49	35
Menstruation	1	29	25	21	51
Menstruation, anomalies of	3	20	23	5	9
Total	4	49	48	26	60
Uterus, fibroid tumors of	21	67	105	186	168
Transfusion of blood	3	7	6	6	2
Placenta prævia	10	59	40	44	59
Pessaries	10	20	14	26	21
Perineum, rupture of	7	28	32	37	20
Pregnancy, extra-uterine	43	55	52	64	77
Phlegmasia, alba dolens	—	6	15	12	23
Puerperal septicæmia	8	11	9	11	22
Uterus, cancer of	33	27	26	52	81
Uterus, cervix, incision of	5	6	1	2	3
Uterus, cervix, laceration of	3	10	12	31	26
Uterus, inversion of	5	25	35	57	49
Uterus, rupture of	9	19	19	16	38
Vomiting in pregnancy	1	7	23	36	14
Lying-in hospitals	20	32	48	106	22
Monstrosities, monsters	—	3	35	52	64

Porro's Cesarean Section with Extirpation of the Uterus appeared as a new operation in 1879 and has since been vigorously advocated and discussed.

The cerebral and systemic effects of renal disease recorded under several headings in the next table show in the aggregate a marked increase in prominence quite commensurate with their importance.

The Forceps were brought forward as a special topic in 1878 by the invention of a new form by Tarnier, and in 1879 by the formal discussion of the extent of their utility at the Obstetrical Society of London; hence the greater figures under these two years.

Tumors of the Uterus continue to attract an increasing interest proportionate to the extension of abdominal surgery.

Extra-uterine Pregnancy has been brought to the front during the past five years mainly through the labors of Parry and Thomas, both Americans.

Puerperal Septicæmia evinces a small but increasing

popularity commensurate with that interest now taken in all diseases attributable to putrefactive changes or the development of germs.

Cancer of the Uterus received an impulse in 1879, which is more than sustained in 1880, by the publication of the alleged curative effect of Chian turpentine in the hands of Dr. John Clay, of England; a claim which has not been corroborated by the experience of other observers. This subject will doubtless fall to its normal level in the present year.

Incision of the Cervix Uteri had its day before the years covered by my tables and is fast sinking into oblivion.

Laceration of the Cervix Uteri and its cure by the simple and admirable operation of Dr. Emmet is the topic of the day, in this country at any rate, but can scarcely be said to have passed from the state of novelty to that of criticism. It is destined to be a fertile topic for several years to come, when it, too, will be assigned its proper sphere — a very restricted one, as I believe — and cease to excite discussion.

The treatment of the Vomiting in Pregnancy by dilatation of the cervix uteri devised by Dr. Copeman, of England, brought this topic forward in 1878 and 1879, as seen by the figures; its decadence in 1880 is manifest.

The subject of Lying-in Hospitals was prolific of discussion in 1878 and especially in 1879, but is now on the wane.

GENERAL CONCLUSIONS.

The above quantitative analysis of obstetric and gynecological literature with regard to nationalities manifests the predominance of America in this branch of medicine. America contributes more journal articles than any other nation; supports by contribution, both literary and pecuniary, as many special periodicals as France, and twice as many as either England or Germany; and carries on as many special societies as all the other countries of the world together.

England, despite the labors of Wells, Keith, Thornton, Barnes, Duncan, Tait, Leishman, and Playfair, is fast losing its preëminence in this branch of medicine, and has recently demonstrated its inability to support even one special journal by the discontinuance of the *Obstetric Journal of Great Britain and Ireland* on January 1st of the present year.

France is exhibiting an unnatural activity under special influences already adduced.

Germany holds on the even tenor of its way, while Belgium, Italy, Spain, Denmark, and Russia are awakening to a more active participation in the advance and dissemination of obstetric and gynecological lore.

I have throughout these pages restricted myself to a quantitative study of the literature. I cannot close without giving in a few words an estimate of the quality of each nation's contributions to the science and practice of gynecology and obstetrics.

Germany unquestionably advances pure science more than any other nation; the papers in its three journals are the most profound and the most critical.

France manifests a great dearth of original ideas, and a most discursive style of discussion, but considerable painstaking historical research. Its journals are prolix and, for the most part, profitless reading, and exceed in number the legitimate demand.

England exhibits a waning interest in this branch of medicine, little originality, but a notable discrimina-

tion in adopting new theories and applying them to practice. Its only special journal died a natural death at the close of the last year.

To America I have no hesitation in according preëminence in this special field. Our countrymen meet the emergencies incident to child-bearing with a quickness of perception and readiness of action rarely seen in other countries. Their ingenuity has led them to devise new operations in gynecology and to carry them out with brilliant results, so that to-day the practice of that branch has reached a stage here far in advance of other nations. Of course our natural aptitudes lead many of us to overestimate the beneficial results of surgery, but taken all in all close observation and study in most of the countries of Europe has confirmed me in the opinion that in obstetrics and gynecology America leads the world.

The two most prominent exponents of our branch in America, *The American Journal of Obstetrics* and the *Transactions of the American Gynecological Society*, present a more happy blending of scientific facts and practical suggestions than is found in any other special gynecological or obstetrical periodicals in the world.

RECENT PROGRESS IN MATERIA MEDICA AND PHARMACY.¹

BY WILLIAM P. BOLLES, M. D.

PAPAIN.

Carica Papaya is a native of the Moluccas, but has been introduced into various parts of India, South America, and the West Indies, where it is valued for its pulpy fruit. It is a small-sized tree of palm-like aspect, with a straight, single trunk and a crown of large palmate leaves in the axils of which are the flowers and fruits. It contains a not abundant amount of white milky juice which can be obtained either from the stem or the green fruit by incisions, as a neutral, opaque, creamy liquid, having a bitterish taste and an odor recalling that of petroleum or vulcanized India-rubber. Under the microscope it appears cloudy and shows a little starch, besides coarser impurities. Upon standing it separates into an insoluble pulp and a colorless limpid serum. Drying converts it into a white hard mass with softer spots upon the surface, of a gelatinous material; iodine colors it yellow, but glycerine preserves it unchanged. For a number of years it has been known that the juice of the papaw tree had a remarkable solvent action upon the animal tissues. The women of Quito used to put it into meat which they were to boil. Endlicher (see Guibourt) noticed that a few drops diluted with water softened the flesh of animals and that a leaf of the tree wrapped around a piece of meat for a single night had the same effect. Wittmak several years ago obtained the juice by incising the green fruits, and made a number of experiments with it, with the following results: a piece of fresh lean beef weighing ten grammes heated in a mixture of the juice and water began to fall to pieces before the boiling point was reached and separated into shreds at the end of five minutes. Hard boiled egg was softened by digestion in the juice. Fifty grammes

¹ Pharmaceutical Journal and Transactions. American Journal of Pharmacy. New Remedies. The Pharmacist. The Chemist and Druggist. The Chemists' Journal. Proceedings of the American Pharmaceutical Association, etc.

of meat wrapped in a leaf of the tree became perfectly tender upon short boiling while a piece not so enclosed remained hard and tough. The dried sap coagulated ten thousand parts of milk at 35° (C?) and, according to H. J. Rose, possesses also the power of converting starch into sugar.

Messrs. A. Wurtz and E. Bouchat in 1879 obtained a white powder by precipitating a concentrated aqueous solution of the juice, by an excess of alcohol, and purifying by redissolving and precipitating again. This, which they ascertained to be the active principle, they named "Papain," and have studied with great care.

It is a stable amorphous powder with little or no odor, and a slightly astringent taste, freely soluble in cold water, becomes slightly turbid upon boiling, is precipitated by the mineral acids and redissolved in an excess of them, also precipitated by tannic acid and by the neutral acetate of lead. It contains a large proportion of nitrogen. In its action upon fibrin it is more energetic than pepsin; quicker and capable of enduring a higher temperature.

Shortly after this Dr. Peckott published an account of some analyses of this substance made by him several years before in Brazil. He, it would appear, had obtained the same principle, to which he gave the name "Papayotin."

An interesting peculiarity in the course of preparation was noticed by Wurtz: he found that when all the liquid had been separated from the coagulated juice the pulp, if again moistened with water, would yield a further quantity of papain greater than the first, and a third and fourth washing yielded almost equally good results. This led him to believe that the papain is produced in the pulp by the action of water upon it, and does not exist, at least in full amount, in the undiluted juice.

The digestive power of papain or papayotin is enormous, and in a more recent paper the same observer has given some instances of it. Dissolved in five thousand parts of water and acidulated with a trace of hydrocyanic acid, one part of pure papain digested nine hundred and eighty out of one thousand parts of moist fibrin, the greater portion of which was transformed into peptone. Again it *liquified* two thousand parts of moist fibrin, and in another series of experiments it was made to partially digest itself.

Its mode of action upon flesh was illustrated by two experiments, and showed "that it formed with the fibrin an ephemeral insoluble compound which by the action of water gives the soluble products of hydration of the fibrin, and being again set free can exercise its action upon a new portion of fibrin."

Papayotin is for sale in very limited quantity as a snow-white, odorless, and almost tasteless powder. It is certainly a promising drug, and if with increased demand it can be supplied sufficiently cheaply may be a useful medicine. It, as is asserted, it will liquify living tissues, its use in exuberant granulations, diphtheritic exudations, and tumors should be tested.

PETIT'S PEPsin.

M. A. Petit has just published an elaborate résumé of the various modes of preparing this substance, and compared them with his own, which he also gives. This consists in carefully washing the stomachs with water, then separating the mucous membrane by scraping with a rounded knife; this is then cut as small as possible and macerated with four times its volume of

distilled water containing five per cent. of alcohol, the mixture is shaken every half hour for four hours; filtered and evaporated rapidly in large flat dishes at a temperature not exceeding 40° C. With sufficient care a pepsin can be made in this way which will *digest* one thousand times its weight of strongly dried fibrin. Sheep's pepsin has only one fourth the strength of pigs'.

ALKALOIDS OF THE SOLANACEÆ.

The close relation of the alkaloids of this family has been long recognized, but owing to the difficulty of obtaining them absolutely pure, their number and high cost, their exact points of resemblance and difference, have not until recently been pointed out. Among those who have succeeded in doing this M. Ladenberg stands easily at the head, and a portion of his results was summarized in the Report in *Materia Medica* and *Pharmacy* for last summer.

He finds in belladonna two alkaloids: one atropine, the other hyoscyamine; the atropine exists in the greater proportion.

Stramonium yields also two alkaloids, the lighter and more abundant of which is hyoscyamine, the heavier probably a mixture of atropine and hyoscyamine.

Hyoscyamus contains two alkaloids, crystalline hyoscyamine and an amorphous alkaloid still under investigation.

Duboisia contains hyoscyamine only.

The synthesis of atropine from tropine and tropic acid was announced last year; he has now obtained atropic acid by the action of cyanide of potassium upon dichlor-ethyl-benzol, and it looks as if atropine would before long be made from materials none of which are yielded by solanaceous plants. In the mean time he had shown that hyoscyamine consisted of two products, hyoscinic acid and hyoscyne, corresponding to the tropic acid and tropine of atropine; these substances he has united to form atropine, as follows:—

- (1.) Tropine from atropine and hyoscinic acid from daturine.
- (2.) Hyoscyne from hyoscyamine, and tropic acid from atropine.
- (3.) Hyoscyne from hyoscyamine, and hyoscinic acid from the same source.

In all three cases a genuine atropine was the result.

One of the artificial tropines, *orytolinetropine*, or, as it is generally called, homatropine, promises to be a moderately useful mydriatic, more transient in its action than atropia itself, but nearly equally strong.

A one per cent. solution of homatropine or one of its salts will dilate the pupil in a few minutes, and allow it to resume its contractile power in twenty-four hours or so. Internally given its action is similar to but less efficient than that of atropine.

MORPHINE AND CODEINE.

Some new chemical properties of morphia have recently been published by P. Chastaing, which are, in brief, that this substance dissolves in the alkalies soda, potash, baryta, and lime, equivalent for equivalent, and forms with them definite crystalline, but easily decomposable, "salts." It is, therefore, in these respects a phenol. The close relation between the composition of morphine and that of codeine has attracted the attention of other chemists for some time, but the actual conversion of one into the other has only been accomplished this year.

The discoverer of the process, M. Grimeaux, has

succeeded in producing codeine from morphine, resembling in all respects the natural alkaloid. This process, which at present is a wasteful one, and accompanied with a great amount of other decomposition products, is to treat the morphia-soda compound with iodide of methyl, exhausting the product with ether, and purifying. Only ten per cent. of the weight of the morphine was obtained as codeine, the rest being chiefly iodo-methylate of the morphine-soda, which in turn could be converted into iodo-methylate of codeine by adding another equivalent of iodide of methyl.

The codeine produced was examined as to its composition, melting point, solubility in water, alcohol, and ether, its salts and crystalline form. Its composition and preparation show it to be a methylic-ether of morphine, and further investigations in progress are showing that morphine may be the foundation of a series of such bases, having to it the relation of ethers. One such was indeed prepared with iodide of ethyl in crystalline plates, and capable of forming salts. M. Grimeaux proposes to call these substances codeines — codo-methylene, codethylene, etc. — Codethylene is a tetanizing poison.

QUEBRACHINE.

Aspido-spermine, the first alkaloid obtained from quebracho, appears to have disappeared and those who had looked to it for the favorable effect in dyspnoea, claimed by Dr. Penzoldt for the bark itself; this fact and the assertion of Frande and Wulfsberg that aspido-spermine was only paytine, has induced Hesse, the discoverer of both, to re-examine the subject. The result of this is to establish the identity of aspido-spermine (which, however, has not yet been crystallized) and also to discover a new alkaloid, quebrachine, of promising activity, and crystallizable, but the only record of its usefulness so far is that in the dose of 0.4 gramme "it killed a rabbit."

ALSTONIA SCHOLARIS; DITA BARK.

Under the name given above a thick, rough, remarkable looking bark has lately been introduced as an antiperiodic and febrifuge. Its value in medicine is by no means proved, but as it has yielded easily some definite chemical principles, it has proved a source of considerable interest to several pharmaceutical chemists, and been pretty carefully examined, with, however, discrepant results. These have been still more confused by the presence of two other alstonias, *A. constricta* of Australia, and *A. spectabilis*, whose barks yield other series of somewhat similar products. At least three alkaloids have been discovered in each, and, what seems discouraging, more are to be expected; if any prove to be of medicinal value they will be again noticed.

THE STABILITY OF CALOMEL.

Chemists from time to time unsettle the nerves of the prescribers of this once famous and still useful medicine by announcing its easy decomposition, or rather its elevation to the bichloride, in the stomach, by some other medicine or even household chemical. M. Verne has recently failed to find any change in the drug in the presence of salt, sugar, or citric acid, but Mr. Ph. Hoaglan, in following out the same investigations, found evidence of the poisonous chloride in mixtures with citric acid after fifteen days, with salt after one hour, and with water even after three hours, but none with calomel and sugar.

It will occur, however, to every one that calomel has probably never existed in the human stomach except in the presence of water and salt, that citric acid as lemonade, and even the tincture of the chloride of iron, are often also present, so that if the reaction were more than infinitesimal not many of our fathers at least would have lived out their allotted days. There really appears to be no medicine so free from danger of poisoning as a single dose of calomel.

RESORCIN, HYDROQUINONE, ETC.

The note upon resorcin in the last report has been justified by subsequent experience, as it is now easily obtainable and in moderate demand. Internally as an antipyretic it is claimed by Professor Lichtheim, of Berne, to be in some respects superior to salicylic acid and quinine; its effects appear to be less durable. Hydroquinone and pyrocatechin have similar antipyretic properties, and may prove useful. Hydroquinone has the advantage in hypodermic use of not being in the slightest degree irritating, and it can be given to the extent of one or two syringefuls of a ten per cent. solution with no more harm or damage than injections of pure water.

PELLETIERINE, ETC.

Since the notice of this alkaloid in the first report for 1880, Tanret has isolated and named the associated alkaloids of pomegranate bark as follows: *Methylpelletierine*, a liquid with hygrometric salts; *pseudo-pelletierine*, crystalline; *pelletierine*, an extremely unstable liquid; *isopelletierine*, also liquid. The most desirable preparation for medical use is the tannate of pelletierine, the full dose of which as a taenicide is 0.4 gramme, followed by castor oil or jalap. It has proved very successful.

XANTHORCEA RESIN; "GUM ACAROIDES."

This resin, like Chian turpentine, had been so long forgotten that none of the present generation had ever seen it. Of late, however, there have been a few inquiries for it, and consequently notices about it are appearing in the pharmaceutical journals. There is no reason to regard it as of any special value.

CORN SILK, STIGMATA MAIDIS.

This easily obtainable material has been considerably employed within the past year or two as a diuretic, and also a "demulcent" in chronic vesical catarrh and in retention of urine. The reports of cases are so favorable that it should certainly receive a trial in these obstinate cases, and may be prescribed in the form of infusion or syrup, or just now may be obtained fresh, and prepared as a domestic remedy.

EXTEMPORANEOUS PILL COATING.

The advantages of coated pills, if they can be obtained without any loss of their medicinal value, are undeniable, and it is one of the greatest opprobriums of modern pharmacy that some plan for covering them quickly and cheaply has not been devised. The trouble is not so much with the material to be used as with the means of applying it, sugar, gum, gelatine, cocoa butter, dextrine, and a dozen other things answering the purpose if properly and freshly applied. Pills, whether coated or uncoated, should be fresh. Moreover, the physician needs to have his own special prescription filled and coated at once. For these rea-

sions the various ready-made pills, however carefully they may be prepared, can never command his unqualified approval. There have been many devices for extemporaneous pill-coating, but none entirely satisfactory or convenient. One of the latest, however, is sufficiently so for gelatine coating as to make it practicable, and if physicians should insist upon having their pills made tasteless would no doubt be followed by more perfect ones. Of course it must not be expected that these hand-made pills will have the finish of the others, but that is of less consequence in view of the fact that the very polishing of sugar-coated pills is one of the causes of their insolubility, and that the desire to prevent the coating from being stained by the mass inside has led manufacturers to varnish their pills before covering them with sugar. The gelatine coated pills appear to be the least objectionable in this respect.

ELASTIC GELATINE CAPSULES.

By far the prettiest novelty of the *materia medica* exhibition of the Massachusetts Medical Society this summer were samples of elastic capsules containing various nauseous and oily medicines. They are composed of gelatine and glycerine, and have about the consistence of the hectograph pad. They are almost as elastic as India-rubber, and seem also as tough. Stretching them considerably does not rupture them, neither does doubling them up, in the case of the larger ones; yet the coating is thin, easily dissolved, agreeable to the taste, and, so far as the writer could see, perfect. Their pliability makes it possible to swallow very large doses at once, a great advantage in regard to economy as well as convenience. They are made up to the capacity of half an ounce for cod-liver oil, and are said to go down as easily as oysters.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. R. T. EDES.

INTERNAL ORIGIN OF CONSTITUTIONAL SYPHILIS.

CASE I. Michael D., aged twenty-nine, laborer, entered City Hospital April 26, 1881, on account of severe pains in his jaws, and nowhere else.

He was well until ten weeks ago, when his right eye became sore. He has a slight eruption on arms and chest, also over his bowels and upper part of thighs. It consists of reddish spots, very slightly raised, a little scaly, and shining on top. He does not seem to know anything about the origin of this eruption. Has had no sore upon the penis, and the glands in the groin, though perceptible, are not distinctly enlarged.

The right eyelid is red, thickened, and partly destitute of lashes. It appears that, feeling some irritation in this eye, probably from coal-dust, a fellow-laborer removed the offending substance with his tongue. He knows nothing of the health of this man. Four or five weeks after this he began to have pain in jaws and sore throat. Now the glands behind angle of right jaw are enlarged.

His ears were examined by Dr. J. O. Green, who found serous inflammation of both tympana, but thought the pain not immediately connected with this. He was treated with protiodide of mercury, iodide of potas-

sium, with morphia, piscidia erythrina, and "tonga" for the relief of the pain. It is not clear that any relief was obtained from the last two drugs.

He was discharged relieved, the pain and eruption having nearly disappeared.

CHOREA WITH ACUTE MELANCHOLIA; AMENORRHEA; RECOVERY.

CASE II. Fannie O., aged seventeen, factory girl. Has not had rheumatism. Had chorea eight years ago. Menstruation began eleven months ago. Three months ago began to be "nervous with twitching of arm and head."

March 3d. Now cannot sleep; appetite poor; bowels constipated; slight headache. Says a doctor told her "her brain was all tired out." (Her occupation was affixing labels to shoes.) Menstruates every two weeks, and generally flows six days each time, with pain. Urine normal.

She was, when first seen, rather a delicate-looking girl, with some slight choreic movements, which gradually diminished in intensity until about March 27th, when they were noted as increasing in violence, and her manner became a little peculiar. The chorea increased until about April 6th, after which it became less marked, when her mental condition gave rise to the more prominent symptoms.

She usually lay in bed with an apathetic expression, saying, when urged, that she did n't feel very well, and that her head ached. At times she became delirious, but there was never any fixed delusion. She was extremely constipated, resisting the action of enemata and the strongest cathartics. Everything done for her at this time in the way of administering food or medicine was vigorously resisted. She became somewhat emaciated; her temperature varied from 98° to 100° F., the pulse from 90 to 120; urine and faeces were passed in bed.

At this time one could hardly avoid the suspicion of meningitis, probably tubercular, although there were never the slightest symptoms of any local paralysis. An occasional cry, which the nurse compared to that of a wild beast, complaints of soreness to touch, and well-marked "tache meningitique" (never a symptom of much value), added somewhat to this probability. Soon, however (in the early part of May), she began to improve, to take more interest in her surroundings, and finally to assist in the work of the ward, as well as to gain appetite and color.

She left the hospital July 13th for St. Luke's Home, whence she was discharged at her own urgent request to go to work. She had menstruated but once in the hospital before her symptoms became severe.

In regard to the medicinal treatment, it was at first chiefly that which we have found most useful in chorea, namely, Fowler's solution. When the choreic movements increased in intensity she took fluid extract of conium in doses increased to seventy-five minims, which had no decided effect, although on one or two occasions she was thought to be quieter after them. For a time all medication was stopped, as the administration of a sufficient supply of food seemed to tax sufficiently the energies of the nurses.

ACUTE PARENCHYMATOUS NEPHRITIS AND CARDIAC MERMER. A CONTRIBUTION TO NATURAL HISTORY.

CASE III. J. C., an employee of a Philadelphia iron company, entered hospital July 17, having been in this

country only about one month. On the 7th of July he became exceedingly drowsy and inactive, and had no inclination to perform his daily labor. Soon began to be troubled with nausea and vomiting, which persisted for several days with only slight remissions. No vomiting at time of entrance; slight fever; excessive thirst; skin very dry; pain and tenderness at epigastrium, but not complained of now; marked swelling of abdomen, legs, and ankles, which has subsided to a considerable extent; frequent micturition, but diminished daily amount, according to patient's estimation about one third normal amount of urine passed; bowels constipated; appetite very poor. For the last few months has been disturbed very much by shortness of breath and palpitation of the heart.

Physical examination: Impulse of heart felt most distinctly just below and within region of the nipple; at the apex the only abnormality is a slight indistinctness of the first sound; slight reduplication or indistinctness of second sound; at left of sternum, in the third intercostal space, was heard a loud systolic murmur, not transmitted.

July 18th. Urine normal color, acid, 1024, and one per cent. of albumen, numerous hyaline and fine granular casts, few casts with crenated blood discs, uric acid crystals in abundance.

July 20th. Urine pale, acid, 1018, one half per cent. of albumen; few hyaline casts; no blood.

July 21st. Urine pale, acid, 1012, and one half per cent. of albumen; occasionally a hyaline cast; considerable mucus.

July 26th. Urine normal color, acid, 1022, and one half per cent. albumen; very few hyaline casts; few blood globules. Cardiac murmur now very much diminished in intensity, and limited to a small area.

July 28th. Urine pale, acid, 1022, one half per cent. of albumen; no casts or blood.

July 29th. Urine pale, acid, 1010, good trace of albumen, normal sediment.

July 31st. Systolic murmur is no longer heard, at present first sound is slightly muffled. Patient discharged well, at his own urgent request, with only a slight trace of albumen in urine. No medicinal treatment of any sort at any time during his stay in the hospital.

OPIUM POISONING; ATROPIA; RECOVERY.

CASE IV. Mrs. B. was admitted to hospital in a comatose condition on the 23d of May, at 4.20 p. m., and was said to have taken laudanum with suicidal intent. An empty one-ounce bottle was discovered in one of her pockets. Could not be aroused. Respirations only 5 per minute; pulse 50, slow, full, and of a "sledgehammer" quality; pupils strongly contracted. One tenth of a grain of apomorphia was administered subcutaneously at 7.30 o'clock, and fifteen minutes later a fifteenth was added. No emesis produced. One half an ounce of wine of ipecac also failed to produce the desired result. At 8.30 p. m. a fortieth of a grain of sulphate of atropia, subcutaneously, was soon followed by a marked rise in pulse from 50 to 100, and the respirations increased from 5 to 17; pupils now moderately dilated. Contents of the stomach were removed by means of the stomach-pump, but nothing was obtained which had the odor of or resembled laudanum. The faradic current was then applied almost continuously, but it would not arouse patient. In about an hour atropia repeated by the injection of

another fortieth of a grain. Respirations 25; pulse remained about the same, perhaps somewhat weaker; pupils still dilated. Between ten and eleven o'clock the pulse began to flag, and become more irregular. Two subcutaneous injections of brandy. At 11.15 p. m. one twentieth of a grain of atropia injected, but was succeeded by no marked change. At twelve m. the conjunctiva, which before had been completely insensible, showed some reaction on being touched.

May 24th. At one a. m. patient had a convulsion, head being drawn back and respiration ceasing for a few minutes. Electricity to face, lips, and chest. Patient soon breathed again. Consciousness restored in the course of two or three hours. During day patient received as nourishment only milk and limewater. Occasional vomiting; hoarseness, sore throat, and a sore feeling all over body complained of.

May 25th. Steady improvement; pulse of good strength; no vomiting.

Examination of specimen of urine drawn on night of entrance showed it to be pale, acid, 1003, and containing a slight trace of albumen, also hyaline and finely granular casts.

The patient remained in the hospital several weeks on account of a burn from a hot-water bag which was overlooked during her unconscious condition. Her general health continued good till about the 1st of July, when she became very much depressed and acted strangely, manifesting signs of mental weakness, and having a suspicious hankering after the medicine closet.

July 12th. Appears very dull and stupid, and is negligent. Urine passed in bed. Tincture of nuxvomica, eight minims, three times a day.

July 13th. Urine, normal color, acid, 1020, faint trace of albumen; epithelium in abundance from the whole urinary tract; few pus cells.

Patient remained in hospital for some time after having recovered from the immediate effects of the laudanum on account of pains in various parts of the body. Opiates were frequently administered, but at length it was discovered that a small amount of quinia answered just as well, and the practice of deception then followed.

Discharged well July 30th.

The two most interesting points in the case, are, first, the great improvement in the symptoms following the use of atropia, which was given in somewhat larger doses than recommended by Bartholow, but in very far from the heroic method of Fothergill. Second, the condition of the urine during narcotism, which was almost exactly that characteristic of chronic interstitial nephritis, low specific gravity, small amount of albumen, and some hyaline and granular casts. This might easily have led to a diagnosis of uræmic coma.

I do not find opium poisoning mentioned anywhere, even in the exhaustive article of Dr. Ellis,¹ as a cause of albuminuria or of the presence of casts. I am, however, now inclined to think that I have seen this association at least once before in a case which was at the time supposed to be uræmic.

There is no reason, however, why many poisons which profoundly disturb the circulation should not give rise to this phenomenon temporarily, just as alcohol sometimes and aconite² have done.

¹ JOURNAL, vol. cii.

² Case of Dr. J. E. Blake, New York Medical Journal, vol. xxi.

SUSPECTED OPIUM POISONING; IMPROVEMENT AFTER ATROPIA; MULTIPLE CEREBRAL HEMORRHAGES; DEATH.

CASE V. L. W., a middle-aged, single man, was admitted to hospital on the evening of the 19th of July in a completely comatose state, with the simple history that he was thought to have taken some preparation of opium two days previous, that day being Sunday; supposed to have lain in his room all this time unconscious.

Respiration jerky and slow, twelve to the minute; pulse very rapid; pupils "pin-hole," and non-responsive; slight reflex sensibility remaining in eyelids.

One thirtieth of a grain of sulphate of atropia given hypodermically, and then a tenth of a grain of apomorphia likewise. No emesis followed use of latter drug. In less than fifteen minutes, however, the atropia had manifested its presence in the circulation, for the pulse arose to 120, and the respirations to 16 per minute. Muscles responded vigorously to a strong electric current, and in a half an hour patient muttered a few words incoherently. He also moved about in bed, and seemed to experience some pain during the application of the electricity; pupils now quite widely dilated during stimulation of surface, but more or less contracted after the withdrawal of the battery. Wine of ipecac given at this period also failed to set up vomiting. Pulse now 142; respirations 14. Then followed a gradual diminution in the pulse-rate, and patient, upon being spoken to loudly, would swallow the brandy and milk offered to him, though with considerable difficulty. Acknowledged that he had taken laudanum, but as to how much he would n't say. Respiration quite deep and noisy; external strabismus of both eyes; face somewhat congested; pupils moderately dilated; reflex sensibility present in both lower extremities; unconscious. At 10.50 p. m., pulse 104; respirations 12; pupils well contracted, apparently as though a fresh quantity of the hypnotic were acting in the system.

July 20th. Breathing that of natural sleep; considerable amount of opposition when eyelids were held open; strabismus still present.

July 21st. At five A. M. patient asked for some brandy, and also complained of feeling very cold. Pupils normal. Urine normal color, acid, 1020, and no albumen, numerous fine granular and hyaline, and occasionally epithelial casts. At 12.15 p. m., pulse 128; respirations 30; and temperature 101.8° F. At 7.15 p. m., pulse 160; respirations 56; and temperature 101.8° F. Cold tub bath now given [95° F. cooled down to 75°] and then followed a reduction of pulse-rate and temperature. Stimulants were freely given by enemata, and patient showed no signs of collapse. At 9.30 temperature had fallen to 101.9° F., and pulse to 132. During night, however, symptoms slowly increased in severity, and death took place at 5.45 A. M. on the 22d.

The following is an abstract of the report of the autopsy by Dr. Gannett:—

Autopsy six hours post mortem.

Calvaria and membranes of brain not remarkable; cerebrum normal; white substance throughout thickly studded with dark-red nodules, varying in size from a pin's head to a split pea, and not to be washed away by water; in corpora striata a few similar nodules.

Heart normal.

Lungs. Pleural surfaces *left*, adherent laterally.

Lung partly contracted, lower lobe dense, and of a dark color. On section surface of lower lobe moist, and on pressure yields considerable aerated serum. Lower portion of upper lobe in area about size of hen's egg, where lung tissue is somewhat denser, and on pressure yields numerous points of pus. Bronchi contain considerable muco-purulent material; mucous membrane reddened and injected. Pleural surfaces *right* also adherent laterally. Lower lobe presented appearances similar to those described in connection with lower lobe of left lung. Lower portion of upper lobe, an area size of lemon, considerably denser than neighboring lung substance, and on pressure there appear on surface numerous large drops of thick pus.

Spleen slightly enlarged, and rather soft. On section showed slight increase of pulp.

Other organs not remarkable.

Diagnosis. Multiple hemorrhages in the brain, chronic adhesive pleurisy, pneumonia from inhalation of foreign bodies, and purulent bronchitis.

CONGENITAL DISLOCATION OF PATELLAS.

BY JOHN SHAPLEIGH, M. D., ST. LOUIS.

AN interesting case of congenital dislocation of both patellas has recently come under my observation in the St. Louis City Hospital. The patient is a man of thirty-nine years of age, of good constitution, and was under treatment for intermittent fever. Both patellas are dislocated outward, resting on the upper and outer surface of the external condyle of the femur. The anterior surface of the latter bone is left uncovered by muscle or tendon as the quadriceps extensor passes on the outer side. Both patellas are movable and may be plainly felt in their abnormal position. They are about the normal size. The patient claims that the deformity is congenital, and states that his grandfather, father, and one of his children had the same dislocation. There was no impediment to walking, and patient served in the army during the war. He has since had the right leg broken in two places, and there is a little limp with that foot. This case is very similar to one reported by Dr. E. T. Caswell, of Providence, R. I., and quoted by Hamilton in his work on Fractures and Dislocations. (Page 767, ed. 1866.) In both cases the dislocation was outwards, and in both there is a certain kind of heredity.

EMPHYEMA IN A CHILD ONE YEAR AND A HALF OLD—ANTISEPTIC OPERATION.

BY JAMES B. AYER, M. D.

ALICE T., a bright child, seventeen and one half months of age, previously healthy, was attacked with pleurisy April 17, 1881, and on the 25th the left pleural cavity was found to be distended with fluid.

She frequently suffered from dyspnea and could not rest upon the healthy side. There was immobility of the left side of the chest, which measured one half inch more than the right side. The heart was dislocated to the right of the median line of the sternum.

Until May 22d (twenty-eight days) I kept her upon as thorough treatment as was permissible without weakening her. Poultries, counter-irritants by iodine, strapping, laxatives, diuretics, and diaphoretics were employed without benefit.

May 22d, after etherizing her, Dr. J. C. Warren aspirated the chest in the sixth intercostal space in the line of the axilla. Finding thick pus he made a free opening, evacuating about six ounces. Carbolic spray was used; a drainage-tube inserted, and Lister dressings applied.

The dressings were changed June 23d, 27th, and 31st. On the first occasion I estimated that less than one half ounce of odorless pus and serum had escaped. At the subsequent dressings there was still less.

On the eleventh day after the operation, finding the discharge slight and all symptoms favorable, I removed the tube and dressed the wound with cosmoline, continuing the Lister dressing. The wound healed rapidly, but forty-eight hours after the removal of the tube she contracted a severe cold, coughed violently, and again an effusion could be detected, but not in large amount. She was also troubled with conjunctivitis.

In ten days, however, there was decided improvement in regard to the cough, effusion, and conjunctivitis, and on the thirty-third day after the operation the effusion had entirely disappeared and air entered the lung freely. The little patient was able to be out of doors, and was rapidly gaining flesh and strength.

The case is of interest on account of the patient's age.

Reports of Societies.

GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED MEETING, FIRST THURSDAY OF JULY.

President, WILLIAM G. WHEELER, M. D., in the chair.

T. M. DURELL, M. D., of Somerville, read by appointment a paper entitled

FUNCTIONAL DISEASES OF THE NERVOUS SYSTEM DEPENDENT UPON DISEASE OF THE UTERUS.

The author first instanced the relation existing between the uterine system and the nervous system in a physiological state, as evidenced by the disorders of the latter incident to menstruation and pregnancy; and hence inferred that disease of the one apparatus must naturally induce disorder of the other; the outcome of which, under the forms of hysteria, catalepsy, and hystero-epilepsy, was the especial subject of the paper.

First of all, the position of Grailly Hewitt was endorsed, that although no connection between the generative function and hysteria has ever been demonstrated, still we believe that a connection exists; and, still further, so far as organic cause can be assigned for the production of the neurosis, it must generally be referred to a chronic flexion of the uterus. Hewitt still further asserts he does not remember a single exception, as respects causation of hysteria, among all the cases he has observed. At the same time it is to be borne in mind we may have hysteria without flexion and we may have flexion without hysteria. We are further to consider that uterine disease acts only as an exciting cause of the hysterical disturbance; back of this must be the irritable condition of the nervous system peculiar to the individual. Hysteria which has lasted for some time, and proceeded to such extent as to get beyond control of the patient, may eventuate in another stage which has been called catalepsy; and the so-called hysteria-

epilepsy is an exaggerated type. The following illustrative cases were given:—

An Irish servant-girl, sixteen years of age, always well up to six months before, when she strained herself by lifting a heavy tub of water and complained that something gave way. Had pain in back and vagina, painful micturition, severe headache, and was unable to stand long at a time. These symptoms, together with painful menstruation, increased until she began to suffer from trembling and vertigo, and finally convulsions attended with a period of unconsciousness. These attacks at last became as frequent as three or four in one day. Examination showed unusual hyperæsthesia of the parts, uterus prolapsed and retroflexed. The uterus was replaced and held in position by a Hodge pessary, which was worn three days, during which time she had no convulsion. Thereafter the instrument became displaced and finally dropped out, two hours after the loss of which a convulsion occurred. Another supporter was introduced and worn some time with complete success. Patient passed out of the care of the doctor for seven months, after which she reported she had worn a supporter all that time and had had no return of the convulsions.

CASE II. A teacher, twenty-four years of age, of nervous temperament, and who had overworked for the past three years. Presented a group of hysterical symptoms, chiefly marked by a dry, harsh cough, lasting several hours and ending in a kind of convulsion, this condition being especially prominent at the time of menstruation. Examination disclosed uterus markedly retroflexed and somewhat prolapsed. Introduction of a pessary, suitably adjusted, resulted in entire removal of hysterical cough and allied symptoms.

CASE III. Dressmaker, thirty-six years of age, suffering from paroxysmal cough, with tendency to convulsion, attended with more or less of coma; menstruation painful and difficult; patient thought she had consumption, but examination disclosed heart and lungs healthy; but vaginal examination revealed fixed retroflexion; reposition was gradually effected by treatment and finally maintained by a Cutter pessary; result, slow and steady, and at last complete, recovery from nervous symptoms.

The author remarked in conclusion that while three cases could not establish much of themselves, they were still of great interest taken in connection with Hewitt's reports; in all was present the invariable condition, namely, flexion of the uterus. If we look upon recovery as simply coincidence, it is surely a remarkable one, that it should take place immediately and invariably upon replacement of the uterus. The connection between hysteria and flexion may be difficult to explain; but there is much evidence both that it is real and that such relation is too often overlooked by the profession.

DR. WARNER asked if any other malposition of the uterus might not give rise to hysterical phenomena; in his own experience had found anteversion more often responsible than any other displacement. Dr. Durell replied that his experience had naturally been limited, but, so far as it went, it emphatically supported the position of Dr. Hewitt, as already declared.

PROFESSOR NELSON, of Chicago, being present by invitation, was called upon by the chair for an expression of his opinion. The doctor replied he would render his opinion on the subject of discussion rather by a series of questions than by positive assertion. And, first, in respect of physiological conditions, what is it in

pregnancy that occasions the nausea, vomiting, the general increased nervous excitement? Do these depend on a modified position of the uterus or upon increased vascularity? And do they originate in an influence emanating from the uterus or from the ovaries, or from both? This problem solved we shall have data for our pathological investigations.

Again, in displacement of the uterus, is it the uterus or the ovaries, which are generally also displaced, that causes the reflex trouble? Were he to venture an opinion, should incline to the belief that the ovaries were chiefly instrumental in originating the disturbances we call hysteria and allied conditions; but still evidence might be presented within the coming year which would lead him to take a different position. One question more. Is not a constant state of hysteria, associated with generative disease, the result of disease of the ovaries?

A woman had worn a sponge as a supporter till there was occasioned dilation of the external os of the size of a silver dollar, while the internal os was of normal size. Every measure of treatment for removal of this lesion failing, at last an operation for cure of laceration was resorted to with entire success. Patient did not come out of the ether well, or suffered from shock of operation, or for some other reason went home a little strange. With first ensuing menstruation showed great nervous excitement, with next menstruation was actually insane, and with the third was markedly insane, and thereafter insanity continued from one period to another. Consultation with an eminent obstetrician brought out the opinion that the case was allied to puerperal mania, and Battey's operation was proposed as means of cure. Examination at this time showed the left ovary enlarged, the right ovary prolapsed, the left broad ligament shortened and thickened. Patient fully understood the significance of the plan of relief proposed, and declared emphatically no doctor should be allowed to "alter" her. She was, therefore, left without treatment, and was subsequently reported to have entirely recovered. Professor Nelson would ask in this case, Was it the prolapsed ovary, or the inflamed broad ligament, or the inflammation of the uterus that caused the mental and nervous trouble?

A PIECE OF SPONGE RETAINED IN THE VAGINA CAUSING SUSPICION OF CANCER.

Dr. W. S. BROWN was reminded by Professor Nelson's experience with the sponge of a case which had fallen into his hands. A woman had received an injury in San Francisco, attended with flooding, to arrest which plugging with sponge was resorted to, the sponge having been, as was believed, removed after a few days. This patient afterwards came East, and was thought to have cancer on account of local irritation and abundant fetid discharge. Dr. Brown, having been called in consultation, detected the offending fragment of sponge, and at once relieved her both of her sufferings and of all suspicion of malignant disease.

Dr. FILLIP doubted if one could read attentively Charcot's great work on Diseases of the Nervous System without being impressed with the force of the evidence adduced making the ovary rather than the uterus chiefly responsible for hysteria and allied nervous distress. Such evidence had perhaps the more weight in view of the fact that the writer was a neurologist, and not strictly a gynaecologist, and so less likely

to be swayed by considerations which might unduly influence a specialist of the latter class. Trousseau goes farther, and identifies hysteria with an aura originating at times in the hypochondriac and again in the solar plexus, still again he distinguishes a fourth variety, namely, that of cerebral origin. The doctor believed he had seen one striking case in an *adult male* illustrative of the last division, that is, hysteria originating in mental and emotional conditions.

Dr. W. S. BROWN added that he believed the ovary to have much more influence than the uterus in causing nervous disturbance, and, farther, he should take different ground from that of Dr. Warner, and should agree with the author of the paper and with Hewitt respecting the position of the uterus, so far as the uterus exerted any influence. Indeed, if we were to regard antelexion causally associated with hysteria, and were to accept the statement of certain authorities as to the frequent tendency to antelexion in young girls, we should expect to find hysteria much more common than it is.

Dr. WHEELER remarked the infrequency of death from hysteria and allied neuroses, and therefore the lack of opportunity afforded the profession of determining by post-mortem examination the condition and relations of the pelvic organs. We have to depend too much on rational symptoms for certainty of pathological conclusion. It is surely true, as Professor Nelson remarked, we cannot have any considerable displacement of the uterus without having also derangement of circulation in the ovaries.

Dr. MARCY objected to the too general and indefinite use of the term hysteria; it is too much like the *amaurosis* of a somewhat earlier day, which condemned many a patient to hopeless blindness who was suffering from temporary functional conditions of the eye. Believed we should yet wholly discard the objectionable term. Had seen closely similar nervous conditions arise from disease located wholly aside from the uterine system; had seen all the symptoms of so-called hysteria manifested in the male suffering from enlarged prostate.

Dr. GIDDINGS, of Gardiner, Me., communicated, through Dr. Marcy, a paper entitled

A RARE CASE OF DOUBLE OVARIOTOMY, ILLUSTRATING TO SOME EXTENT THE VALUE OF ANTISEPTIC SURGERY,

of which the following is an abstract:—

A woman, aged forty-seven years, had passed the change in life, presented an enlargement of the abdomen, which was diagnosed ovarian tumor. Had examined her twice before within a year, and in April, current year, prepared for an operation. Her surroundings being regarded unfavorable, a thorough process of disinfection was entered upon a week before the operation was performed. All dispensable pieces of furniture were removed from the patient's room, and all that must remain, with curtains, walls, etc., were covered with a twenty-five per cent. carbolic spray. Instruments and clothing of surgeon and assistants were also treated in the same way immediately before operating. Strength of spray used during operation fifteen per cent. Tumor was exposed in the usual way, and the presence or absence of adhesions determined by sweeping a silver male catheter around it,—none existed. The sac, unilocular, was emptied and drawn out, when it was found that it was attached

from the utero-vaginal junction to the fundus of the womb by a broad pedicle. This was secured by a chain-stitch of carbolized silk, a ligature of the same was then thrown about the whole, a clamp was applied and the mass severed. Satisfied there was no danger of hemorrhage, the clamp was removed and the stump dropped into the pelvic cavity.

Turning attention to the other ovary, it was found enlarged, in size about that of a coffee-cup, and presenting papillomatous growths, of which description was given. This tumor was also removed.

Double ovariectomy has been less often done in Europe than in this country, Spencer Wells having accomplished it but twenty-five times in his first five hundred cases. The author farther believes, from his review of the literature of the subject, that the coexistence of two entirely distinct tumors, as in the present case, is very rare; Dr. Homans has met with five papillomatous growths in the course of forty-three ovariectomies. The nature of papilloma is to return speedily to the other ovary, involving the peritoneum and contiguous structures and organs in its development, hurrying the patient to a fatal issue. The present patient is of course secure as respects the other ovary, and her very satisfactory convalescence, increase of weight, etc., give encouragement she may escape the usual order of things. The paper closed with a circumstantial account of the recovery of the patient from the operation.

Dr. MARCY said the prime question concerns the pathological nature of the growth of the second ovary.

Dr. WHEELER had seen one case of papilloma in the last eighteen months; it was removed, but the patient died. Had assisted Dr. Thorndike in a case where papilloma was developed in the cyst; case took on afterwards what appeared like a malignant character, and patient died in three months. In the question of such possible complication with the ovarian tumor the books mislead; cancer is more common than we are given to understand; had himself seen within a few years four or five ovarian tumors showing cancerous complication at time of operation. The question of the future immunity of Dr. Giddings's patient will be of importance for future inquiry.

Dr. W. S. BROWN asked if ascites was present in Dr. Giddings's case. In all cases of papillomatous tumor, so far as he was informed, where there was grave suspicion of malignancy, there was complicating ascites. If this feature were absent he should judge favorably of the future chances of the patient. Spencer Wells gives a similar opinion. Again, as to cancer associated with ovarian tumors being more rare than the books state, he should believe it was rare as a primary affection, but not rare as an outcome of cancer developed elsewhere.

Dr. MARCY could not answer the question as to the presence of ascites, but should judge from the record of the case that it was absent. The doctor recalled the case of a woman with ovarian tumor who burst a cyst while dancing, and when it came to the operation the papillomatous masses were found sprouting from various points independently of the place of its original development.

UTERUS AND OVARIES REMOVED BY GASTROTOMY.

On call for pathological specimens, Dr. MARCY showed the specimen of a uterus enlarged by multiple fibroids, with both ovaries having undergone cystic de-

generation, which he had removed by gastrotomy nineteen days previous.

Mrs. S., aged forty-four years, for six years an invalid, confined to the bed, her sufferings, chiefly pelvic, almost never absent. Emaciation extreme. Husband and patient both longed for relief at almost any cost and risk. Operation done in Dr. Marcy's private hospital, with all antiseptic precautions. Heat of patient maintained by hot water circulating in a rubber coil placed under the entire body, with view of prevention of shock by abnormal lowering of temperature. In the removal of uterus and ovaries the division was made elliptically, and thus the stump was covered by peritoneum, which was secured by animal ligatures and dropped back into the abdominal cavity. External wound treated as in ovariectomy. Convalescence satisfactory, temperature being maintained at about 99° F., with the exception of once or twice for a few hours, when it exceeded 100° F. Hemorrhage was controlled, and no raw surface allowed in the abdominal cavity. This would appear an important advance in the extirpation of the uterus.

Dr. W. S. BROWN noted the important step, in Dr. Marcy's operation, of covering the stump with peritoneum, so that the risk of septicæmia was much reduced. Spencer Wells has lately adopted this precaution, and regards it of essential value as a safeguard.

Dr. MARCY rejoined that for such investment of the pedicle the profession was largely indebted to Dr. H. R. Storer; for Spencer Wells uses a kind of clamp which divides the pedicle into five or six parts, about each of which a double ligature is applied, causing a multiplication of knots. We used a needle that will allow us to sew double. Tait does not believe it possible to so occlude the pedicle of a uterine tumor that it is safe against hemorrhage. The doctor reported his clitorodectomy case as still doing well.

Dr. M. L. BROWN showed the product of an abortion, with the following history: A married woman had been absent from her husband for a number of months. On the day of her return she began to menstruate, but the husband insisted on intercourse. The ovum, which the doctor exhibited, was extruded twenty-seven days after the coitus, and was of interest both on account of definiteness of date and as representative of what is not often seen, namely, a fœtus of one lunar month's development.

Dr. Brown also illustrated a ready device to which he had resorted under circumstances of flooding to incipient exsanguination. The doctor had no syringe with him, and the patient could retain nothing on the stomach. He therefore fashioned a cone out of bar soap, in the cup of which was fitted a ball of the same material. Into the cup was placed a drachm of Squibb's ergot, the ball applied as stopper, and the instrument then pushed into the rectum in such way as to insure its rupture when it had well passed the sphincter. The hemorrhage was almost immediately arrested, whether by virtue of the remedy or otherwise, and the patient saved.

On motion, the thanks of the Society were voted to Dr. Giddings, and he was nominated for corresponding membership.

— A correspondent of the *Lancet* tells of the recovery of a boy of seventeen after having his "right arm with scapula attached dragged clean from his body."

Recent Literature.

A New Form of Nervous Disease, together with an Essay on Erythroxylon Coca. By W. S. SEARLE, A. M., M. D. New York, Fords, Howard & Hurlbert, 1881. Pp. 138.

This little book, written by a homeopathic physician, consists of two essays; the first concerning a symptom or group of symptoms which he has dignified as a new disease. Several cases are briefly described, and analyzed. There is no cause, however, for speaking of the collection of symptoms found in these cases as a new disease.

A brief abstract of the section devoted to an analysis of symptoms will enable us to understand the subject more clearly. We are given two central phenomena, one of shock, the other of venous congestion. Either of these may antedate, and, perhaps, postulate, the other. The shock may burst upon the patient without any previous congestion of the head, others may suffer from various forms of headache or from congestion of the cerebellum for months and years preceding the shock. Peculiar occipital sensations did not appear till after the shock.

The author thinks that the profession have not fully appreciated the character of the shock, to which he refers as a profound and serious symptom, giving rise to the conviction that instant death is impending, and terrifying the patient; it is generally referred to the occiput and is accompanied by vertigo only when thus situated. When in the cerebrum or the ears vertigo is rarely present.

In many of his cases the author found symptoms which he refers to a congestion of the cerebrum or cerebellum. These symptoms were not uniform, and were chiefly uncomfortable sensations in the head, a sense of weight and fullness, sometimes pain in the back of the neck, more rarely headache, cold hands and feet, slight disturbance of vision. There is no good reason why these should be referred to congestion of the cerebellum.

Under the sections of pathology and diagnosis Dr. Searle has chiefly discussed the theory of discharging lesions and epilepsy, saying many things which might be criticised if they were worth it, and neglecting to explain how the shock may be produced.

Dr. Mitchell¹ mentions these cases of shock among other disorders of sleep, and says, "The clinical relationships of these attacks are to epileptic fits, and to those well known, and, I may say, normal phenomena of a certain movement of the body at the moment of going to sleep, or even at other times." He then speaks of the attack as a "more or less violent discharge from a centre of general sensation."

While it is possible that the centres of sensation may be abnormally excited so as to give rise to various sensory phenomena, it is not easy to imagine how such excitation could produce all the phenomena met with in many of these cases. As the symptoms are very easily and simply explained upon another hypothesis it is not necessary to have recourse to the above-mentioned theory.

It is well known that in certain diseases of the labyrinth of the ear, more especially when the semi-circular canals are affected, peculiar symptoms arise, which

are thus briefly enumerated by Trousseau, — the patients are suddenly attacked with vertigo, nausea, even with vomiting, they may fall to the ground after having walked a short distance like an intoxicated person, they rise with difficulty, remain pale, are covered with a cold sweat, almost lipothymic; and these symptoms may be frequently repeated. Since Ménière first described these phenomena they have been carefully studied by many observers. Toynbee saw giddiness and other cerebral symptoms caused by pressure of wax upon the membrana tympani and by syringing the ear. We have seen such phenomena from these causes, but preferred to quote others in support of these statements. The pressure of the wax or the impulse of the water upon the drum of the ear communicated through the ossicles causes the stapes to exert a pressure upon the vestibule which is communicated to the fluid in the semi-circular canals. A sudden and forcible contraction of the tensor tympani muscles would also produce pressure through the stapes upon the fluid in the labyrinth. Such contraction would also be accompanied with a sensation of sound, which would give to the patient the impression of a shock, an explosion in the head, or a blow upon the head; this, with the accompanying vertigo, nausea, etc., form one feature of the combination of symptoms which in this essay is called "a new form of nervous disease." Sometimes there is only the sense of "shock" without vertigo or nausea, a spasmodic contraction of the muscles belonging to the Eustachian tube would explain such a shock. In conversation with Dr. C. J. Blake in regard to the phenomena under consideration he mentioned that he had experimented in applying electricity to the Eustachian tube; the result was a sensation as if a blow had been received upon the side of the head. As the tensor tympani takes its origin from the inside of the Eustachian tube it is quite probable that both muscles may be affected by spasm at the same time.

The other phenomena mentioned by Dr. Searle as belonging to his new form of nervous disease are such as are very common in cases of nervous exhaustion from over-work or other causes or in dyspepsia.

The section on treatment is quite interesting as showing the comparative inefficiency of specific, that is, homeopathic, treatment. In regard to coca the author says, "I cannot regard it as antipathic in the strict sense of the word. It certainly is not homeopathic, but it is still (however it may act) one of the most reliable remedies for the palliation, and, perhaps, cure, of this malady." It appears that of twenty-one cases the result was not known in four; two still remained under treatment; three were in the practice of other physicians who make no mention of the treatment; nine took coca and were either cured or the recovery commenced while using that drug; another recovered while using phosphorus. Only five received homeopathic treatment alone.

Homoeopathy seems to have failed in treating the condition under consideration. The account of the treatment in the cases reported is very defective. It is not possible to judge from the account how much influence diet, rest, and the regulation of the patient's life generally had to do with the recoveries.

This little essay does not deserve so long a notice, but being dignified with a quasi-endorsement in the shape of a short note from Charcot, and being apparently an honest effort to explain a certain phenomena, it has seemed to us better to give it some notice.

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 15, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

FIRST ANNUAL REPORT OF THE NEW YORK STATE BOARD OF HEALTH.¹

By far the largest portion of this volume is taken up with the appendix, and the first report given after that of the executive and finance committee is that of the standing committee on registration and vital statistics. The committee has devoted itself energetically to two distinct branches of labor, namely: First, the correct and thorough registry and tabulation of the movement of the population of the State, as to its increase by birth, its extension by marriage, and its decrease by death; and, second, the faithful record of those diseases which have made up the death-rate of the year with a review of reported epidemics -- their character, location, and severity, together with the measures advised for their suppression or prevention in the future. In furtherance of this work the committee has distributed a number of circulars, forms, and copies of laws to city and town boards of health, physicians, and health officers, clerks of school districts, and town clerks and supervisors throughout the State; and complete records of a number of epidemics, detailing their primary causes, severity, and extension, with maps of localities affected, have already been secured, while the system of vital registration provided by the State Board of Health has been put into successful operation in a considerable portion of the State.

The report of the committee on quarantine, external and internal, includes a very interesting *résumé* of the history of quarantine laws enacted from time to time for the protection of the port of New York, and enters to some extent into a discussion of some of the mooted points respecting the general subject of quarantine. The principal diseases against which the Laws and Regulations of Quarantine at the Port of New York are directed are, yellow fever, small-pox, ship fever, and cholera, and a full account of the methods at present adopted with unqualified success against these affections is given. The latter part of the report of the committee is devoted to the subject of internal quarantine, and after pointing out the dangers which are liable to arise from the neglect of proper precautions during the prevalence of contagious and infectious diseases, mentions some of the measures which the committee have adopted for the suppression and prevention of such diseases in the various portions of the State. The diseases recognized by the health

authorities as contagious or infectious, and which require sanitary supervision to prevent their introduction or mitigate their severity and limit their propagation where they prevail are enumerated as follows: malignant cholera, yellow fever, typhus fever, typhoid fever, relapsing fever, puerperal fever, cerebro-spinal fever, small-pox, diphtheria, dysentery, and measles.

In the report of the committee on public institutions a detailed statement, with illustrative diagrams, is given of the system of ventilation, heating, drainage, and water-supply of the State Lunatic Asylum at Utica, under the charge of Dr. John P. Gray, which is pronounced the most perfect of any public building that the members of the committee have ever visited. The committee on sanitary legislation, rules, and regulations, furnish in their report a complete set of model sanitary regulations, which have been devised after the most mature deliberations, and copies of which have been distributed to the health authorities in every district of the State.

After the reports of the standing committees follows the excellent address, entitled, *What the State Owes to the People*, which was delivered before the American Public Health Association at its eighth annual meeting in New Orleans, December, 1880, by the Hon. Erastus Brooks, one of the State commissioners of health, and then comes an abstract of the minutes and transactions of the Board up to the date of the report. In the report of the secretary the duties of the Board, which have been under the constant cognizance of that officer, are grouped as follows:—

(1.) The establishment of official relations by communications and conference with existing and organizing local boards of health in the State.

(2.) The communication of such information, requests, and incentives to these local authorities as, in their official capacity, should organize and maintain local boards of health where there are or at the time were none.

(3.) The exchange of information and practical suggestions, concerning local duties and sanitary interests, with the proper local authorities, especially those of towns, villages, and counties.

(4.) The systematic daily disposal of official papers and business of the central office of the board, in accordance with the by-laws and the statutes, and with this view of local duties and local authority.

(5.) The organization of the methods and system for the registration of births, marriages, and deaths, and of the prevalent diseases throughout the State, and the organization of the central bureau of registration of vital statistics.

(6.) The maintenance of correspondence and useful relations with other State boards of health and with the National Board.

The remainder of the volume is taken up with the special reports upon prevalent diseases previously referred to. The first of these are in reference to diphtheria; and the occurrence of the affection in an isolated wilderness region in Hamilton and Fulton counties furnished an opportunity for unusually exact

¹ Continued from page 235.

observations upon the origin and discernible causes of this disease in a district where, as it is believed, no case of it had ever before been seen. In the report of the epidemic at Geneva, by Dr. N. B. Covert, some very interesting observations, based upon the analysis of the waters, are given in regard to the relations of the disease to the pollution of wells.

Dysentery comes next, and in the detailed report of a limited house-epidemic at Southampton, Long Island, during the summer of 1880, by Dr. P. Brynberg Porter, of New York, it is conclusively shown, from the careful investigations made, that contamination of the drinking water by privies and cess-pools, rendered more than usually pernicious by certain meteorological conditions which prevailed at the time, was undoubtedly the source of the trouble.

Then follow some reports of house-epidemics of typhoid fever and cholera morbus in different portions of the State, and others showing the effect upon the public health of abandoned canals, stagnant ponds, obstructed water-courses, and other sources of malaria; while the concluding section of the volume is devoted to the account of small-pox as it prevailed in West Troy and neighboring towns, and the measures that were adopted for its suppression. From the above brief sketch it will no doubt be seen that, as was stated at the outset, the report affords sufficient evidence that a satisfactory amount of work was accomplished by the Board during the first six months of its existence, as well as that it gives assurance of increasing usefulness in the future; and certainly no one who at all appreciates the patent fact that "public health is public wealth" will be inclined to begrudge the very trifling expenditure on the part of the State which is necessary for the maintenance of such an organization.

MALARIAL INFLUENCES IN NEW ENGLAND.

We took occasion lately to refer to the increasing development of malarial influences in various parts of New England. The next annual report of the Massachusetts Board of Health will present a paper by Dr. J. F. A. Adams, of Pittsfield, on the appearance and spread of malaria in the western part of this State, which, if throwing no light upon the origin and mode of propagation of the poison, will at least give all the facts of the phenomena as they have presented themselves in that neighborhood. This paper will be read with interest.

The July bulletin of the secretary of the Connecticut State Board of Health contains the following in regard to malarial diseases:—

"Malarial diseases appear to have taken a step eastward and northward, as a death from malarial fever is reported from Norwich. I have not yet learned of any east of the Thames River. In many places they are reported as increasing, as in Bloomfield, New Canaan, Unionville, and other towns in various parts of the State, while others report decrease, as in Clinton and Colliard. Collinsville claims entire exemption from malaria in every form unless imported, as thus far no

cases have originated there. If flowing large areas and alternately covering and exposing the bed of the pond produced malaria we should have it here. If vegetable decay alone produces it we should have a fearful epidemic at Poquonnoc Bridge, instead of scarlet fever, as the river was absolutely choked with vegetable substances decaying and alternately covered and exposed. Yet no case of malaria has ever originated in this town."

The progressive spread of malaria in this part of the country, where most of the conditions usually supposed to be conducive to its propagation are apparently absent, might easily become a fit subject of investigation by the National Health Board.

MEDICAL NOTES.

—When dispensers of patent remedies take to sanitation something startling is to be looked for, but the true inwardness of some of the advocacy of particular schemes is not often so clearly brought out as in a recent issue of an Arkansas paper. A certain "doctor," "at the solicitation of a number of medical men and other scientists," delivers himself on sewerage to the effect that he would—

"Flash the lightning through cess-pools that would blast all spores and germs. The probable fact has not yet been mentioned, but electricity, that now conveys our thoughts and speech, and gives light and health, will finally be the di-infecting agent of poisons on and under the earth, as it is now the purifier of contaminated clouds."

Possibly the fact has not been mentioned, but on reading in the same paper that the doctor is the author of an electro-medical institute for the cure of some thirty-five diseases "not amenable to ordinary treatment," the source of the inspiration that would set thunderbolts to cleaning sewers becomes obvious. — *Sanitary Engineer*.

—According to the director of the Bureau of Statistics at Vienna out of 102,831 individuals who have passed the age of ninety-nine years 60,303 are women, and only 42,528 are men. In Italy 241 alleged centenarian women are found for 141 men of that age.

—Under the heading of Philanthropy and Typhoid Fever the *Sanitary Engineer* contains the following:—

"The English colony at Rugby, Tenn., has lately had a severe experience, proving once again that the most philanthropic intentions are no protection against the consequences of the neglect of proper sanitary precautions. A severe epidemic of typhoid fever, with twenty cases, according to the Cincinnati *Commercial*, out of a population of less than four hundred, has overtaken the colony in consequence of careless and filthy habits. This epidemic is attributed by the physicians to the pollution of the drinking-water of the hotel where many of the colonists got their meals. The water was obtained from a shallow artesian well close to the hotel, and also from a cistern near by supplied with rain-water from the roof. The water

in this cistern became very impure from the throwing of slops on to the roof which drained into the well. There are no water-closet accommodations and the dejections of the sick were thrown away in the slops, which ran through a ditch into a cess-pool fifty feet from the hotel. This cess-pool was very filthy, giving out an unendurable stench, and it is believed its contents easily found their way into the cistern and well. It is also supposed that dejections from the first case of fever entered the drinking-water. The disease was especially centred about the hotel, deriving its supply from these sources, where there were three sick, and there were also three other patients in the annex a few blocks away. The colonists have altered their practice since the physicians have called these facts to their attention; their water is now brought from streams at some distance, and probably they will not again need to be taught that philanthropy and dirt are not congenial."

— Specially in your walk in life avoid theological discussions and politics. All of you have, I trust, confidence in some form of Christian religion, and what I would say to you is, support your own form of belief and everything connected with it to the best of your means; sympathize with and aid your own clergyman, and all other clergymen of whatever denomination, for our profession and theirs can do much and good work in common; be at all times tolerant to the religious opinions and feelings of others, and keep in remembrance one great principle of the Christian religion, "Let brotherly love continue." — *Professor Annandale.*

NEW YORK.

— Dr. A. E. M. Purdy, president of the New York County Medical Society, recently caused the arrest of several persons on charges of practicing medicine without legal diplomas, and all the cases were brought up at the Jefferson Market Police Court. One of the prisoners was held in three hundred dollars bail to answer, but the others, who were drug clerks, known to have prescribed over the counter, were simply reprimanded by the court, and discharged.

— To obtain the best possible plans for the new hospital, which is to be erected in Brooklyn by Mr. George I. Leucy, at an expense of two hundred and forty thousand dollars, the committee in charge of the building arrangements, consisting of Dr. Louis Pilcher, Dr. A. E. M. Purdy, ex-Mayor Samuel Booth, and Mr. John French, have decided to award three prizes, amounting in all to fifteen hundred dollars, to be divided among the architects who furnish them with the three best plans. The ground donated for the hospital covers an entire block, and the buildings will consist of an administrative department, three or four stories in height, and several pavilions of one and two stories. A chapel will also be erected on the grounds, and the institution will be under the control of the Methodist denomination.

— Dr. Elwyn Waller, chemist to the Board of Health, has just made an analytical examination of the water from twenty-eight wells in the Twenty-Third and Twenty-Fourth Wards, the district recently

annexed to the city from West Chester County, and has found that in only two instances is the well-water really good. Six wells were pronounced unsafe, seven excessively unsafe, and the rest doubtful.

Miscellany.

LETTER FROM WASHINGTON.

LOCATION OF LEAD IN THE LIVING HUMAN SUBJECT BY ELECTRICITY.

MR. EDITOR.— Permit me to put on record through your valuable journal a discovery made in 1875 by which lead can be located in a living human subject by means of electricity. I quote from my article of that date:—

"I have discovered by a series of experiments with the electro-magnetic battery that a current of electricity thrown through the human living body gives rise to great uneasiness when passing through lead, amounting to absolute pain if the power of the battery is increased, and the current through the lead is continued any length of time." "Having in my profession but limited means of verifying or extending the experiments upon this most interesting subject, it must be left for extension in the hands of those whose field of observation is so much more extended, and who have the material for experiment so much more abundant."

My first experiment was upon my own person, having had the misfortune to receive a full charge of shot from a friend's gun whilst woodcock shooting. Each pole of the battery should have a wet sponge attached; placing one pole at the base of the brain or base of the spinal column, a distinct feeling of uneasiness is experienced when the other pole is placed so as to pass the magnetic current of electricity through the lead, and this uneasiness is quickly rendered decidedly painful if the current is continued long and increased in power, although that increased power will give no uneasiness when applied on other parts of the body.

My second series of experiments was made upon an old soldier, kindly sent to me by Dr. Norris, U. S. A. This ball was lodged four or five inches from the spinal column and a little below the fifth rib, as near as I can remember, and could be felt with the hand. Mr. McGill says "the feeling was of a stinging character," and when a stronger current was passed through the lead "caused me to jump in my chair!"

My third experiment was with Col. Morrow, of Gen. Sherman's staff. Dr. Basil Norris, Surgeon U. S. A., says of the ball in Col. Morrow's case: "The point of entrance of the ball was near the groin; the current located it on the inner aspect of the thigh near the knee." Col. Morrow says: "I am satisfied your location is a correct one."

My fourth experiment was on John Tehan at the Soldiers' Home, by courtesy of Dr. Huntington, U. S. A., in charge. The ball in this case, says Dr. Norris, "entered about the centre of the right gluteal region; the current located the ball near the hip-joint." Mr. Tehan says you found the most painful point in your experiment on him."

In the second and fourth or last case the current was longer continued and the power of the battery increased, so as to prove beyond a doubt the presence of the lead, the patients being strong men. Dr. Norris says: "Your experiments with the electro-magnetic current to find a bullet lodged in the living body, as

witnessed by me, were successful in defining a painful or burning sensation supposed to be produced by the presence of the ball." Dr. D. L. Huntington, Surgeon U. S. A., and acting surgeon of the Soldiers' Home, through whose courtesy I performed the experiment at the Soldiers' Home Hospital in presence of himself and Dr. Norris, says: "I have no hesitation in saying that I think your experiments on August 7th on the person of Tehan, an inmate of the Home, demonstrated the presence of a metallic body at or about the region between the greater trochanter of the right femur and the tuberosity of the ischium. The presence of this body was repeatedly evidenced by a sharp pricking pain, with some shock when the magnetic current was made to traverse the regions."

In all these experiments the lead was encysted, the wounds having occurred more than twenty years previous to this date. In recent wounds I have no doubt the most gentle current would indicate the presence of lead; and with a little care the location could in most cases be reduced to the diameter of one inch, which would be sufficiently accurate for the surgeon's purpose. Having located the region occupied by the ball in the manner described, the two poles of the battery should then be brought as nearly as possible opposite to its position, so as to pass the current of electricity directly through the lead, when the stinging, burning sensation will be distinctly experienced by the patient, increasing in intensity, even to a shock, if the current is continued and the power increased.

H. NICHOLS WADSWORTH, D. D. S.

1028 VERMONT AVENUE, WASHINGTON, D. C., August, 1881.

RECENT ADVANCES IN SURGICAL TREATMENT OF INTRAPERITONEAL TUMORS.¹

BY T. SPENCER WELLS.

I should not have thought it necessary, after the progress which has already been made in abdominal surgery, to insist at any length upon what I believe now to be a fundamental principle or rule of practice accepted and adopted by all the most experienced and successful operators at home and abroad, if I had not been fiercely attacked by that singular society, which, admitting the right of man to kill all the lower animals, to use them for food, their skins for clothing, their feathers for ornament, to make them labor for our convenience, denies our right to use them for any scientific purpose, or in the hope of benefiting the human race. These curious philanthropists persistently attack me because I sacrificed a few rabbits, dogs, and guinea pigs in the year 1859 in order to demonstrate, beyond all doubt, for all time to come, the fact that human life may be saved, and lifelong suffering prevented, by an improved mode of uniting penetrating wounds of the abdominal cavity. They argue that results obtained in animals are no guide to what may happen in man; that my observations were not new, and that some believe they are not true; that some think ovariectomy has, on the whole, rather shortened than lengthened the life of woman; and that its mortality has not been lessened by the knowledge gained by my experiments on animals.

Of course, I have not taken any notice of these attacks; but I wish to show you exactly what I did, and leave you to judge whether or not the human race

has been served by the death of about a dozen animals twenty years ago. Here are the specimens which I have been permitted to bring hither from the Museum of the College of Surgeons. Before I hand them round let me tell you exactly what led me to make the experiments. The first three women upon whom I performed ovariectomy all recovered. The fourth died without, as I thought, any good reason why she should have died.

I was naturally much interested in the post-mortem examination, and I obtained the invaluable service of my friend, Dr. Aitken, to make it. We found that the state of the inner surface of the wound was far from satisfactory. At that time, instead of the sutures I have used of late years, I used harelip-pins and twisted sutures to unite the wound; and we saw at once that some of the pins on the inner aspect of the abdominal wall were bare; the cut edges of the peritonæum were retracted; a portion of intestine was in contact with the wound, the impress of which was obvious on the surface of the gut. Some coagula of blood, and an abundant, consistent, lymph exudation upon the peritoneal surface of the intestine, corresponded to the edges of the incision and the surface of the wound. Recent lymph glued the opposing surfaces of the intestines to each other. I saw at once how much better it might have been if the peritoneal edges had been accurately brought together, and had united, and thought of doing this in my next case. But I found careful instructions in text-books and treatises to avoid the peritonæum, just as some few surgeons even now fear that they may set up peritonitis, or that pus from the tracks of the sutures may get into the peritoneal cavity. So I determined rather to make the experiment *in corpore vili* than on women. Dr. Richardson kindly helped, by narcotizing the animals, some with puffball and some with chloroform.

In these specimens, where the divided edges, or rather surfaces, of peritonæum have been pressed together, you see that the smooth serous inner coat of the abdominal wall is perfectly restored. You cannot see the stitches on the inside, though plainly visible on the skin; and there is no adhesion of intestine or omentum. When skin or mucous membrane are divided their edges must be brought together to secure direct union. If they be inverted union is prevented. The exact opposite holds good with serous membrane. The edges should be inverted, and two surfaces of membrane pressed together, so that the sutures are not seen; and the effused lymph makes so smooth a surface that even the line of union cannot be seen. In these specimens you can only discover it by the line of sutures in the skin. But mark the contrast in these other specimens, where the peritoneal edges were purposely excluded from the sutures. In every case where the animal was not killed within a day or two intestine or omentum adheres to the inner surface of the abdominal wall, thus completing the peritoneal sac, at the great risk of intestinal obstruction, or of permanent discomfort to the survivor, to say nothing of a want of firm union and subsequent ventral hernia. One can hardly understand the so-called reasoning which insists that this should not be demonstrated once for all in a few narcotized animals, but that we should grope our way to the realization of the truth through the sufferings and by the dissection of a series of women. You can examine the specimens now, and they will remain in our College Museum, and will serve, I trust, to dispel

¹ Extract from a speech delivered at the opening of a discussion to the Surgical Section of the International Medical Congress.

any doubt which may still be felt as to the best mode of uniting penetrating wounds of the abdominal wall. And I will go still further, and say that whenever edges or surfaces of peritonæum are divided or separated they should, if possible, be reunited. Peritonæum must be opposed to peritonæum; and this can only be done by drawing it over the pedicle, or stump, or divided parts, and fixing or uniting it as an envelope by a line of sutures or by the uninterrupted suture. I have already urged this persistently in my works on diseases of the ovaries; in the Hunterian Lectures at the College of Surgeons in 1878; in a paper on the removal of uterine tumors, brought before the British Medical Association at Cambridge last year; and in some recent papers.

THE TREATMENT OF GALL-STONE BY OLIVE OIL.

SOME of our readers may recall the mention of the use of olive oil as a remedy for gall-stones a year ago. The JOURNAL at that time called attention to the mention of the treatment in Flint's Practice of Medicine, and the opinion there expressed that the masses passed were intestinal concretions. The supposed cure has gone the usual rounds and it gives us great pleasure to reproduce from the *Lancet* the following communication, by Dr. R. Shingleton Smith, Physician to the Bristol Royal Infirmary:—

In the *Lancet* of September 18, 1880, and in the *Medical Record* of March 15, 1881, are reported cases of gall-stone treated by the administration of large doses of olive oil, with very remarkable and satisfactory results. It is stated that in both cases hundreds of gall-stones in various stages of disintegration were discharged from the bowel, and that the patients were permanently cured after one or two doses of olive oil, although repeated attacks of biliary colic had been present for twelve or eighteen months before. The writer in the *Medical Record* considers it certain that in olive oil we have a substance which, when given in a dose of six or eight ounces within an hour, has the power of bringing away the contents of the gall-bladder, and apparently without pain, and the calculi are almost disintegrated in the process.

A patient, a medical man between sixty and seventy years of age, has been subject to attacks of biliary colic at intervals for the last six or seven years. The pain comes on suddenly, and is relieved by nothing so well as injections of morphia hypodermically. Of late these attacks have been more frequent, more prolonged, and more exhausting, especially as they are generally accompanied by considerable vomiting, and great disturbance of the heart's action, with prostration. On learning the effects of olive oil in the cases reported he determined to put the matter to the test in his own case; he reasoned that it might do good, but could do no harm. Accordingly he procured a quantity of the finest salad oil, and took about six ounces within the space of one hour, sipping it slowly from time to time in small quantities and stopping as soon as any feeling of nausea was present. The result on the following morning he describes as follows:—"There was no action from the olive oil or the confection of senna taken very early this morning, but an enema brought down fæces of almost stony hardness, and hundreds of green masses of all shapes and sizes from canary-seed to a good-sized horsebean; some were imbedded in masses of hardened

faces, but floated as soon as separated; others were separate and were found floating on the surface of the water. The color was pale green; some of them were translucent. All were soft and flattened on pressure. The six ounces of oil appear to have been digested, saponified, or emulsified, for there was no appearance of oil floating in the water of the enema." Many of these masses were preserved for examination, but hundreds were thrown away. Three days afterwards they were submitted to me for examination. They were then soft and greasy to the touch, but still coated with a greenish-colored film, which disappeared on touching any spot with the finger. They had not become dry by exposure to the air, and warmth increased their tendency to liquefy, so much so that on being carried in a pill-box in the waistcoat-pocket they melted away, and left simply a greasy stain in the box and in the pocket. In consistence and texture they resembled very soft soap, and on being cut with a knife the section had a mottled appearance and the knife was greasy. No nucleus was found in any of the masses, and they were all of similar texture. The shape varied considerably; they were for the most part rounded and oval, but so easily molded that this varied with the treatment. They were found to dissolve readily in boiling alcohol, leaving only a small residue; they also broke up in boiling water, forming an opalescent solution, at once cleared by ether. The solution in alcohol gave little or no precipitation on cooling; no crystals of cholesterine were precipitated on cooling the hot solution in alcohol. The masses were not acted on by strong sulphuric acid or by iodine. The sediment in the cooled alcoholic solution consisted of a whitish powder insoluble in water, cold or hot, in nitric acid, or liquor potasse. Drops of the ethereal solution evaporated on a slide left oil globules, not quite liquid oil, but opalescent and thickened to a semi-solid consistence; under the microscope these oil drops were seen to contain minute acicular crystals, like margarine.

My examination led me to the conclusion that these masses were not composed of cholesterine, and that the principal element in their composition was oil, possibly in a state of semi-saponification. In order to get an unbiased opinion as to their chemical nature, I submitted a few of the masses to Professor Ramsay, of University College, Bristol, for chemical examination. His report is as follows:—

"They consist for the most part of olive oil, and it is impossible to separate from them any substance resembling cholesterine, for the separation of the two is a very difficult problem, the same solvents dissolving both. But under the microscope it is possible to see with a very high power that the consistency of the masses is due to the presence of a great number of very minute crystals, which appear to polarize light to some extent, and which somewhat resemble crystals of cholesterine. The fatty masses on burning give a trace of residue, and that trace shows the presence of a very minute quantity of phosphoric acid by the most delicate test that can be applied, namely, ammonium molybdate. All that I can venture to state, therefore, is that the masses are not a soap, but chiefly olive oil full of small crystals, which may or may not be cholesterine. I should require a very much larger quantity than you have given me to decide the point chemically."

The results of Professor Ramsay's examination quite coincide with mine in these respects: (1) That the composition of these bodies is totally different from that

of an ordinary gall-stone, and (2) that olive oil is the principal substance in their composition. It may, therefore, safely be inferred that they are *intestinal concretions resulting from the administration of the oil*, and that they have not been discharged from the gall-bladder by any mechanical or chemical action of the large dose of salad oil.

At the time of my writing the patient is laid up with another and more severe attack of biliary colic than he has ever had before. The bile-duct is completely obstructed, and the skin very deeply jaundiced. He followed up the first dose of oil with a second, but, in spite of this, continued to have pain in the region of the liver, which at last culminated in the present severe attack.

It must be inferred from the experience of this case that we are still unprovided with a remedy with the virtues which have been of late attributed to olive oil.

A more complete chemical examination was not possible, as the masses had undergone liquefaction and dispersion when a further quantity was inquired for.

ETHER DRUNK.

DURING the present week great publicity has been given to an instance of dead drunkenness from the use of ether. The subject, a French gentleman, is what is incorrectly called "an ether dipsomaniac." He inhales the vapor of ether freely and constantly, and is unable to manage his own affairs, so readily and steadily does he intoxicate. He is a gentleman of good means and of thirty-five years, and when he is under his favorite spell he commits mad freaks, which, if they do not make the angels weep, give more trouble than weeping to the cabmen, the police, and the civil magistrates of Paris. He has been more than once under restraint, but he relapses when he is free, and now his friends pray that he may be interdicted and that a family council may manage his property. This history is strange, but not singular. Ether intoxication is a recognized form of narcotic mania, and has been known to affect the whole of a district. After Father Mathew, by his surprising eloquence, converted the thousands of his countrymen and countrywomen to total abstinence, one of his districts converted from whisky and other alcoholic drinks was reconverted to ether. At Draper's Town, in Ireland, a man followed the good Father and married his work by teaching the natives not to inhale but to drink ether, and so effective was the teaching that for about forty years there has been in Draper's Town and about it an ether-drinking community. Dr. Richardson, who visited the district in 1877, found the custom still prevailing, and has described how the ether drinker, first washing out his mouth with cold water, gulps down from two to three ounces of sulphuric ether without wining, and in a few minutes is in the height of his frenzy. The madness is short, but active while it lasts; and although it does not seem to have been followed by any of the serious consequences related about the Parisian devotee, it is not very safe, for Dr. Morewood, of Draper's Town, has met with several cases in which dangerous insensibility has followed ether-drinking, and has, if we remember correctly, known four deaths from it. Curiously enough to the uninitiated, the effect of ether in setting up organic disease in those habituated to it is comparatively trifling compared with the effects pro-

duced by the habitual use of alcohol, so that in regard to injury of a chronic kind in the vital organs ether is the most merciful tyrant to its victims. It kills them sometimes, but it does it—as poor Frank Buckland tattooed his salmon—as if it loved them, and it does it off-hand. — *London Lancet*.

A CASE OF SUICIDE BY DYNAMITE.

THIS curious case of suicide is reported by Dr. Leadman in a late number of the *British Medical Journal*, and, as he suggests, may prove of interest in a medico-legal aspect.

J. H., aged fifty-six, a well-sinker, of irregular and intemperate habits, on July 12th concluded a "drinking bout" of several weeks' duration. During this debauch, one evening, when in company with other men, a man of the party lost a purse containing seventeen pounds. A statement made by H. led to the apprehension and trial of a respectable farmer, who had been present when the purse was taken. The charge was proved to be groundless. On the 13th, the day of the trial, H., though sober and perfectly rational, failed to appear as a witness, making some excuses to his wife and son. About noon, at the time when he should have been in court, he walked into a garth at the back of his residence, and a neighbor in an adjoining field, observing him suddenly fall, went to his assistance. He saw blood issuing from his mouth, and at once sent for me. I found the mouth full of blood, and, on examination, the soft palate torn away, the fauces rent, the tongue detached and mutilated, the teeth broken off and splintered, the superior maxillary bones separated and extensively fractured—the fractures extending to the floors of the orbits. Blood was extravasated into the eyeballs, the lower eyelids, and the upper portions of the cheeks. The inferior maxillary bone was broken into about twenty pieces. The skin of the cheeks and lips was intact, save a few scratches on the internal surface of the latter. There was no charring of the tissues. A box of matches was found in his pocket, and one, partly consumed, close to his mouth where he fell. In his trade he used both cartridges and caps containing dynamite, and was well acquainted with this terrible explosive. One of these he had placed in his mouth, and, after igniting the short fuse attached to it, deliberately awaited the result. He survived the lesions two hours, remaining unconscious the whole time. The evidence given at the inquest was considered by the jury conclusive as regarded his sanity, and a verdict of *felo-de-se* was returned. Although I have both inquired of my friends and examined several works of reference I have failed to discover a similar case recorded.

"LA FOLIE À DEUX."

Brain reproduces from the *Gazette des Hôpitaux* the account by Dr. Régis, of the asylum of St. Anne, of a form of insanity to which he gives the name of "la folie à deux." He recognizes two varieties of the disease: first, that in which, of the two individuals who become insane, the one first attacked communicates his insanity to the second, who remains on the borderlands of alienation, and may recover on being released from the dominating influence; second, more

complex and rare, where both are subject to the same form of madness, having been exposed to the same morbid causes and predispositions.

The first division has been fully described by MM. Lasègue and Falret, and may be summarized in the following statements:—

Only one of the two is insane, he having communicated his delusions to the second by a certain moral and intellectual superiority. The individuals have lived in intimate contact. The active agent communicates part of his insanity to the passive, but between the two there is a line of demarcation, the first only being legally insane. Moreover, the latter speedily recovers when removed from the influence of the former.

The second division comprises those cases of true folie à deux presenting the following characteristics, as observed in five pairs of cases:—

The two individuals become insane simultaneously. They are hereditarily predisposed to mental alienation. They live in intimate and constant contact. The exciting cause operates on both in the same way and at the same time. The mental manifestations resulting are substantially the same; the hallucinations and delusions are the same. Separation of the two is not attended by beneficial results.

Folie à deux may be defined as a monomania, usually of persecution, happening simultaneously to two

individuals, the causes of which are, first, hereditary predisposition; second, intimate and constant contact in daily life; third, an exciting cause acting on both.

SENTIMENTALITY ABOUT VIVISECTION.

THAT pleasant French traveler, Henri Havard, tells us that on his first visit to Holland he used to see quite often the heavy barges called *trekschuiten* dragged along the canal by a big dog and a woman harnessed to the same rope, while the man steered. On a later voyage he missed the big dogs and saw only the woman, or perhaps two women, tugging at the heavy boat. Informing himself as to why this change in the habits of so conservative a race as the Dutch, he learned that the local Society for the Prevention of Cruelty to Animals had secured the passage of an act prohibiting the harnessing of dogs; so the women had to do it all themselves!

In similar style, the antivivisectionists of England and this country are striving to prevent some very few of the lower animals from being used for the purposes of science, when the inevitable consequence of their success would be that the progress of medical knowledge—which means the relief of pain, the restoration to health, and the preservation of life—would thereby be retarded. — *Medical and Surgical Reporter*.

Deaths reported 2709 (no reports from Brooklyn, Chicago, or New Orleans); 1345 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 1023, diarrheal diseases 583, consumption 324, diphtheria and croup 139, lung diseases 119, typhoid fever 104, scarlet fever 53, malarial fevers 47, whooping-cough 32, small-pox 23, cerebro-spinal meningitis 21, measles eight, erysipelas six, puerperal fever six, typhus fever one. From *scarlet fever*, New York 23, Philadelphia 10, St. Louis and Pittsburgh six, Baltimore and Buffalo two, Boston, District of Columbia, Milwaukee, and Worcester one. From *malarial fevers*, St. Louis 15, New York 13, District of Columbia seven, Baltimore five, Philadelphia three, New Haven two, Pittsburgh and Nashville one. From *whooping-cough*, New York nine, Boston four, Philadelphia, Baltimore, Pittsburgh, and Providence three, St. Louis and Cincinnati two, District of Columbia, Buffalo, and Fall River one. From *small-pox*, Pittsburgh 11, Philadelphia nine, New York three. From

cerebro-spinal meningitis, New York eight, Philadelphia, St. Louis, and Cincinnati two, Baltimore, Pittsburgh, Providence, Lowell, Fall River, Lynn, and Chelsea one. From *measles*, New York five, Baltimore two, Pittsburgh one. From *erysipelas*, New York, St. Louis, Baltimore, Buffalo, Salem, and Chelsea one. From *puerperal fever*, New York, Philadelphia, St. Louis, Baltimore, Salem, and Newburyport one. From *typhus fever*, New York one.

Twenty-five cases of small-pox were reported in Pittsburgh; diphtheria 21, scarlet fever two, in Boston; diphtheria 10, scarlet fever one, in Milwaukee. Dysentery is still very prevalent in Buffalo.

In 43 cities and towns of Massachusetts, with a population of 1,104,991 (population of the State 1,783,086), the total death-rate for the week was 26.74 against 22.85 and 28.67 for the previous two weeks.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 3, 1881, TO SEPTEMBER 9, 1881.

CAMPBELL, JOHN, Lieutenant colonel and surgeon, medical director of the department. Granted leave of absence for twenty days. S. O. 91, Department of the South, September 2, 1881.

WHITE, R. H., captain and assistant surgeon. Granted leave of absence for twenty days from 5th inst. S. O. 125, Department of West Point, September 2, 1881.

THE censors of the Suffolk District Medical Society will meet for the examination of candidates for membership of the Massachusetts Medical Society, at 19 Boylston Place, on Thursday, September 22d, at three P. M.

SIXTH ANNUAL MEETING OF THE AMERICAN ACADEMY OF MEDICINE.—The American Academy of Medicine will meet in New York on Tuesday, September 20th, at three o'clock.

BOOKS AND PAMPHLETS RECEIVED.—A Treatise on the Diseases of the Nervous System. By James Ross, M. D., M. R. C. P. Lond. Illustrated with Lithographs, Photographs, and two hundred and eighty Woodcuts. Two Vols. New York: William Wood & Co. 1881. (A. Williams & Co.)

A Manual of Histology. Edited and prepared by Thomas F. Satterthwaite, M. D., of New York, in association with Drs. Thomas Dwight, J. Collins Warren, William F. Whitney, Clarence J. Blake, and C. H. Williams, of Boston; Dr. J. Henry C. Simes, of Philadelphia; Dr. Benjamin F. Westbrook, of Brooklyn; and Drs. Edmund C. Wendt, Abraham Mayer, R. W. Andon, A. R. Robinson, W. R. Birdsall, D. Bryson Delavan, C. L. Deane, and W. H. Porter, of New York city. With one hundred and ninety-eight Illustrations. New York: William Wood & Co. 8vo, pp. 478. (A. Williams & Co.)

Report of the Commissioner of Education for the Year 1879. The Prescriber's Memoranda. New York: William Wood & Co. 1881.

Manual for the Physiological Laboratory. By Vincent Harris, M. D. (Lond.), and D'Arcy Power, B. A. (Oxon.) New York: William Wood & Co. (A. Williams & Co.)

Treatment of Varicocele by Excision of Redundant Scrotum. Illustrated by New Instruments and an Account of fifteen Successful Cases. By M. H. Henry, M. D. New York: J. H. Vuil, 27 Great Jones Street. 1881.

Lectures on the Surgical Disorders of the Urinary Organs, delivered at the Liverpool Royal Infirmary. By Reginald Harrison, F. R. C. S. Second Edition, considerably enlarged. New York: William Wood & Co., Publishers, 27 Great Jones Street. 1881.

The Opium Habit. A Clinical Lecture. By Charles Warrenton Earle, M. D. (Reprint.)

The Springfield City Hospital. Annual Report for 1880.

Transactions of the State Medical Society of Wisconsin for the Year 1880.

The Harrowgate Waters: Data, Chemical and Therapeutical, with Notes on the Climate of Harrowgate. By George Olliver, M. D. Lond. London: H. K. Lewis, 136 Gower Street, W. C. 1881. (Presley Blakiston, Philadelphia.)

Lectures on the Diagnosis and Treatment of Diseases of the Chest, Throat, and Nasal Cavities. By E. Fletcher Ingals, M. D. With one hundred and thirty-five Illustrations. New York. 1881. 8vo, pp. 437. (A. Williams & Co.)

Landmarks, Medical and Surgical. By Luther Holden, assisted by James Shuter, F. R. C. S. From the Third English Edition, with Additions, by William W. Keen, M. D. Philadelphia: Henry C. Lea's Son & Co. 1881.

Chemical Analysis of the Urine, based in part on Casselmann's Analyse des Harns. By Edgar F. Smith, Ph. D., and John Marshall, M. D. With Illustrations. Philadelphia: Presley Blakiston. 1881. (A. Williams & Co.)

Majority Report of the Committee on the Subject of Lunacy Commissions in the United States and Foreign Countries, their History, Aims, and Results. From the Proceedings of the Connecticut Medical Society, 1881.

Lectures.

CLINICAL LECTURE ON THE DISEASES OF THE NERVOUS SYSTEM.¹

BY PROFESSOR ERB, LEIPZIG. REPORTED BY GEORGE L. WALTON, M. D.

SYPHILITIC TABES DORSALIS. — TRAUMATIC INJURY TO NERVES ACCOMPANIED BY DEGENERATIVE REACTION. — RADIAL PARALYSIS FOLLOWING FRACTURE OF THE HUMERUS. — APOPLEXY FOLLOWED BY HEMIPLEGIA.

GENTLEMEN, — The first patient is a man, thirty-one years old. The subjective history consists of numbness in the feet and easy tiring on exertion, together with pains in the joints. Twelve years ago he had a syphilitic sore.

On testing the sensations of his feet and legs we find his perception of a touch by the finger or pin lessened and retarded. His appreciation of differences of pressure and temperature over this region is very poor, and he does not feel so weak a Faradic current here as in other parts. On pinching the skin, however, the sense of pain is found to be acute and rapid. With the eyes closed the patient is unable to tell in which direction we bend his toes. He has then diminished tactile pressure, temperature, and electrical sensibility, but no analgesia. The plantar and cremaster reflexes are absent as well as the tendon reflexes in the lower extremities. The abdominal and pupil reflexes are normal. On the patient's crossing his foot over his knee we see a slight loss of coördination. He cannot stand on his toes with his feet together, and he cannot keep his balance with his eyes shut. His gait is ataxic, but when we test the separate muscles of his leg we find them quite strong. There is nothing abnormal to be found about the head, trunk, or upper extremities. His sight is good, and the eye movements, including accommodation, are normal. He sleeps well, and there are no irregularities in the function of bladder, rectum, or genital apparatus.

This is a typical picture of tabes dorsalis, and there is nothing else with which to confound it. Sensations of lower extremities (excepting that to pain) diminished, loss of coördination without special loss of power, muscle sense lessened, and tendon-reflexes wanting. A subjective history of paræsthesia, weakness, and "rheumatic" pains.

The cause, especially as we can elicit no history of excesses of any sort, must be considered syphilis, which is the fact in about ninety per cent. of the cases.

The next patient, a man twenty-two years old, received, about five weeks ago, a wound in the right wrist, and since that time has complained of motor and sensory disturbances in the hand. The wound was sewed up, and the surgeon stated that he had sewed the ends of the nerves together. The scar extends from the posterior ulnar surface of the forearm, about three inches above the wrist, obliquely over the front of the arm, ending inside of the line of the radial artery.

The radial nerve is not affected, but the functions of the median and ulnar nerves are seriously interfered with. Sensations of touch, pressure, temperature, and pain are entirely wanting on the palmar surface of the hand and fingers. On the back of the hand these sensations only remain over the radial half of the hand, the thumb, index, and half of the middle finger. The

last phalanges of these fingers are also anæsthetic posteriorly, being furnished by the median nerve. All the thenar and hypothenar muscles are paralyzed and atrophied. The flexion of the fingers is greatly impaired, but as the flexor muscles receive their nerve supply above the point of injury, the loss of flexion must be due, not to paralysis, but to the flexor tendons being involved in the cicatrix. The only movement possible in the thumb is flexion of the last phalanx, which is done by the flexor longus pollicis.

Electrical examination shows complete degenerative reaction in the track of the median and ulnar nerves, that is, the nerves react neither to the Faradic nor galvanic current, while the muscles fail to react to the Faradic, but to the galvanic react more strongly than normal, especially to the anode closure. On kathode closure a slow tonic contraction is seen, and on anode closure a similar but far stronger one. We see, on testing the corresponding muscles of the other arm, a much stronger contraction on kathode closure than on anode.

Trophic disturbances are marked, the skin is thin, the fingers pointed, and peculiar blisters appear on the backs of the fingers, which the patient attributes to hot water, but which are probably due really to injury to the trophic nerve fibres, such alterations in the epidermis often resulting, after injury to nerves, from an amount of heat or violence which in health would produce no appreciable results. This view is strengthened by the fact that the water did not feel particularly warm to the patient's other hand, in which there is no loss of sensation. Sometimes these trophic disturbances appear without any apparent exciting cause.

The electrical examination shows us exactly the pathological condition of the nerves and muscles. If we could examine them at this stage we should find the following conditions: In the nerves the myeline escaping from the nerve sheath in drops of fat, a multiplication of cells in the sheath itself, an atrophy of axis cylinders, and a thickening of the neurilemma. In the muscles we should find atrophy of the fibres with multiplication of cells and nuclei, indistinctness of cross lines, and increase of connective tissue.

As to prognosis, if the nerves were really properly sewed together the case should recover, though slowly. Traumatic injuries to nerves accompanied by degenerative reaction requiring months, say three, four, six, or longer for return of function. The difficulty in flexion will probably be permanent, owing to the restriction of the tendons.

The next case is one of radial paralysis. The patient, a man fifty-two years old, broke his humerus about four months ago, and the radial nerve was involved in the callus, and its functions completely lost. The callus has now been laid open and the nerve freed. The extensors of the hand and wrist and both the supinators are paralyzed. When the arm is extended supination is impossible, though in the semi-flexed position supination is perfectly performed by the biceps, which is the real supinator in this position together with the supinator brevis when intact. On telling the patient to flex the arm while we resist the movement at the wrist, a slight trace of contraction is seen in the supinator longus. At the last examination this was not present, and is a very favorable sign, probably indicating a regeneration in the nerve, exhibited first by restoration of the function of the nearest muscle supplied by it. The muscles affected are flabby

and atrophied to a greater degree than can be explained by the long use of splints.

The Faradic current produces no contraction either when applied directly on the muscles, or indirectly on the nerve. The galvanic current has no effect on the nerve, but applied to the muscle produces a strong slow contraction, more marked and longer on anode closure than on kathode, that is, degenerative reaction is present. The sensation, curiously enough, remains intact over the surface of the hand supplied by the radial, though more or less anesthesia exists over the surface of the arm supplied by the external cutaneous.

The persistence of sensation in this part of the hand may be explained in one of two ways; either the sensory fibres of the radial nerve have escaped injury, which is highly improbable, or this is a case of vicarious function, and sensory fibres from other nerves in this region have developed their functions to an unusual degree, to atone for the loss of the radial fibres proper.

The nerve and muscles in this case are in a similar state of degeneration to that described in the last case, as shown by the electrical reactions, but probably regeneration has begun to take place, and new young fibres are appearing in the degenerated nerve. These young fibres always respond to the stimulus of the will before they are electrically excitable from the periphery. This is illustrated by the fact that this patient can contract his supinator longus although we cannot cause it to react to the Faradic current.

This case will, like the last, prove very tedious, but will probably recover, as the nerve has been laid free, and signs of regeneration have already appeared.

This woman, aged thirty-nine, had an attack of unconsciousness about nine months ago, lasting three days, after which her left side, including her face, were paralyzed. There was loss of sensation on that side which only lasted a few days. There were no cramps, no trouble in speech or swallowing after the attack, and no loss of mental power as far as can be learned. She has, however, since that time been rather deaf, the other special senses remaining intact. In common terms, the patient has had an attack of apoplexy followed by hemiplegia.

Proceeding to examine her systematically we find she can open and shut her eyes, protrude her lips, and laugh quite normally. She extends her tongue in a straight line, and the uvula is not deviated. She chews and swallows perfectly and has no disorders of sensation about the face. The left arm hangs flaccid with entire loss of motion. The fingers are pointed, the skin glossy, and the nails distorted. The tendon reflexes in the arm are much exaggerated, a contraction of the muscles following the stroke of the percussion hammer on almost any point of the wrist, hand, in fact over the clavicle and the spine of the scapula. The sensations are intact.

The sensations on the left leg are unaffected. The patient has a spastic gait, and the movements of the left foot are limited, the muscles are somewhat contracted. The tendon reflexes are increased, though to a less degree than in the arm. The plantar reflex is diminished. This relation of tendon and skin reflexes is the common one in such cases. The right arm and leg are normal in sensation, motion, and reflexes. Electrical reactions are everywhere normal.

This is a typical picture of an apoplectic attack; a period of unconsciousness followed by paralysis, improvement in all paralyzed parts excepting the arm, sensations normal, no atrophy, electrical reactions normal, increased tendon, and decreased skin reflexes.

As to the origin and seat of the lesion. It is either an embolus or a hæmorrhage in the right hemisphere. Examination of the heart reveals nothing abnormal, and there are no signs of aneurism anywhere. These facts speak against embolism, as well as the three days' coma, and the probable diagnosis is that of hæmorrhage.

The seat of the hæmorrhage is certainly in the centre of the brain in the region of the great nuclei. That it is not at the surface is shown by the completeness of the hemiplegia, the lack of cramps and convulsions, the improvement of the symptoms, and the non-existence of psychical or special sense disturbances beyond the deafness.

The contractions and increased tendon reflexes show a degeneration in the pyramidal column of the cord secondary to the lesion of the brain. The completeness of the hemiplegia shows that the lesion must be seated at the convergence of the fibres from the various parts of the brain, that is, in the capsula interna. As there are no disturbances of sensation the anterior portion only of the capsule is now affected, though the deafness indicates, perhaps, that some fibres posteriorly are injured. And of course the temporary loss of sensation shows that at the time of attack the posterior third of the capsule was not entirely unaffected by the hæmorrhage, though it speedily resumed its function of conveying sensation. Laterally the seat of the lesion cannot be so closely defined.

Aphasia rarely occurs after injury of the right hemisphere, though two autopsies have been made establishing the fact that it can take place. In both these cases the patients were left-handed. Our patient is right-handed. The prognosis is unfavorable.

THE MANAGEMENT OF THE INSANE.¹

BY CHARLES F. FOLSOM, M. D.,

One of the Trustees of the Danvers Lunatic Hospital.

So recently as the time when I went to an insane asylum as an assistant physician, I was strongly advised that in order to maintain my own sanity I must keep out of the wards and away from the patients as much as I could; and yet I was assured that to persons already insane the constant association with diseased minds and the removal from healthy influences were the most potent means of restoring unsound brains to their former equilibrium. The part of the hospital in which the officers lived was alone provided with the amenities and associations of ordinary life, the absence of which in the patients' portion was actually supposed to constitute some obscure mental tonic conducive to recovery.

There was not an insane asylum in our State where the visitor was not oppressed in almost every ward with the dreariness of excluded sunshine, the gloom of almost prison seclusion, the weariness and despair of monotonous idleness, or the aggravated excitement arising from excessive confinement and restraint. This cannot be said to the same extent at the present time, and such vast improvements have taken place in the treatment of insanity in the last ten years, in our State at least, that many of the popular complaints against the institutions with whose care we are charged apply

¹ A paper read before the Hospital Trustees Association, at the Northampton Hospital for the Insane, July 12, 1881, and printed by vote of the Association.

to a condition of things which obtained in the past but does not form part of our asylum management at the present time, if it ever existed; and yet if there were no hospitals for the treatment of mental disease in existence, and if we had not the traditions of the last four centuries' humiliating record of superstitious fear and consequent neglect or abuse or unwise treatment of the insane to mislead us, probably no one would think of constructing — unless possibly for a few very violent inmates — one of our modern insane asylums, either for the care of the curable insane or for the safe keeping of those that may have become more or less permanently dependent upon the bounty of the State or the kind care of relatives and friends. I do not wish to undervalue the devoted labors which have so enormously advanced the comfort, if not the cure, of the insane in recent years. I simply desire to state the well-known fact that the light of modern research has not yet penetrated the walls of our hospitals for the insane to the same extent that it has pervaded every other branch of medical science.

From a purely medical point of view the accumulation of large numbers of the insane in a single building is most certainly a mistake, to such an extent that it is at least doubtful whether cures are not thereby sacrificed. As a question in social economy, institution-life is to a considerable degree demoralizing, both as regards its effect in making people shirk the responsibility of taking care of their helpless or troublesome relatives, and in diminishing the disposition to self-help on the part of the inmates. Still, the demands of the community will increase rather than diminish for protection by the State from its dangerous and irresponsible members, who again need special care to prevent their being neglected or abused in their helplessness.

The huge modern insane asylum is the inevitable outcome of the demand of the rate-payers for low taxes, and of the necessity of providing accommodation for a class whose numbers in all States far exceed the capacity of the buildings designed for them. The insane asylum is a necessary evil, too large to secure the best results from medical treatment, and in the construction of which "economy" — a mistaken economy, I think — is too generally considered, although in certain directions there is also wasteful extravagance. Some of the newest in England are far worse than our own in this respect. In my own opinion the asylums of Germany and France are vastly superior to those of Great Britain and this country in the matter of scientific study of mental disease. As a general rule, with individual exceptions, England, and, to a much greater extent, Scotland, are far in advance of the rest of the world as regards the naturalness and freedom from unnecessary restraint in the asylum life of their insane, so much so that it is still doubtful whether some of their extreme experiments in that direction, their open-door system, for instance, should be, or ever will become, general. In Massachusetts, although we are, like England and Scotland, doing very little for the scientific study of insanity, and perhaps exceed Germany, if not France, in our lack of employment and adherence to old methods of treatment, yet we work harder for the personal comfort and gratification of the individual tastes of our insane patients than any other country.

It is not the time now, however, nor the place, to discuss the comparative treatment of the insane in various lands, nor to consider in detail differences in race,

in customs, and in the disease itself, which will always give to this perplexing question of the care and cure of insanity, that so many uninformed and inexperienced persons feel competent to treat exhaustively, almost as many solutions as there are countries in the world. We cannot expect the New England mechanic to submit to the bullying that the Scotch or English pauper lunatic thinks is the natural order of things, nor to consent to be hired out, like the Belgian at Gheel, to work for a peasant at a dozen or two dollars a year, nor to accept, like the German, the repose of tobacco and beer as a substitute for that restlessness and impatience of restraint which the American thinks indispensable to a free citizen of the republic. At present I would like to bring before you a few practical points which I hope may serve as a framework upon which shall be raised some far better plans than those which I suggest.

Our surgeons and physicians would not for a moment tolerate a fever ward, a lying-in room, and an operating theatre in a building which served at the same time for an almshouse, an idiot school, an asylum for paralytics and epileptics, and a refuge for the chronic insane. We have in our insane asylums precisely this great incongruity, in regard to which Dr. Baneroff, of Concord, in his last report, has so well stated the best opinions of the present day, that I cannot do better than quote him at some length, as follows: —

"Insanity does not transfer its subjects into a new category of human beings with identical wants. It is one of the mistakes of the uninformed to assume this, and this assumption was carried into the plans of most of the asylums of earlier date. In these some features, such as liability to violent impulse, failure of self-control, and consequent need of safeguards, were sufficiently recognized. These features were emphasized out of due proportion to the number of cases demanding an exceptional architecture. This fact accounts for the rigid monotony of most of these buildings. It has too much limited the range of classifications, both as to number and character, and tended to reduce all to a dead level, with insufficient regard to individual peculiarities. The effect of this has been to render very difficult the attempt to vary the influences and adapt them to the indications growing out of individual constitution, habits of life, and form of disease, in a satisfactory degree. With resources thus limited, it is not rare to find any possible classification of a patient beset with grave objections, or lacking in some important demand in the case. That objection will sometimes consist in the necessity of subjecting the patient to the society of incompatible associates, sometimes in the imposition of limitations of personal freedom, demanded, indeed, for the safety and welfare of others, but unnecessary and irksome to the one in question. Again, it may consist in the necessity of exposing the patient to the constant presence of morbid manifestations in others, tending to counteract the best-planned remedial measures.

"The list of difficulties might be greatly extended, but this is sufficient to suggest that the relative association of the insane in an institution bears a very grave relation, not only to the final results of treatment, but to their peace, comfort, and contentment while under care. It is no less an object to protect the morbidly sensitive mind from all adverse influences than to provide the best direct remedial measures.

"Much thought has been bestowed and diverse opinions held upon the subject of classification in asylums,

but the fact will remain that a given environment will impress the sane and the insane of the same class in much the same manner; and this fact is a strong reason why classification should grow out of individual conditions rather than an arbitrary principle. Large wards composed of persons in advanced stages of disease are practicable, and the contacts mutually harmless, but it is otherwise with recent attacks, in which many of the faculties are in healthy operation, and the sensibilities morbidly alive. With such a single adverse influence, whether it be a thing seen or heard, or an inference from the report of the senses, is liable to become important in the final issue. For example, it cannot be harmless for one in acute melancholia to be associated with those who represent mental disease in its last stages unrelieved. The mind, already leaning towards despair, will be sure to see its own end pictured in the fellow-patient. This I have often observed. The same may be said with regard to the convalescent classes. Here, too, the nervous sensibilities are impressible, and the condition calls for hope-inspiring surroundings. . . .

"Two persons may agree in a single symptom, such as being maniacal, and so far as that symptom goes they are in the same class; but they have *other* traits demanding consideration. One may be offensively vulgar, profane, or obscene, while the other may be strictly observant of purity of thought and propriety of speech. . . . So of two other persons, one may have been bred in gross and repulsive habits, while the other shares the refinements of the home from which he comes; still, they may agree in some circumstance, which, on this broad plan of classification, compels their association. Disease or previous character may render one treacherous and untrustworthy, while another may be normally responsible. In any considerable numbers there is great diversity in the need of personal restrictions. Safety demands them for *some*; others need little or none, but are annoyed and humiliated by them. Again, the previous manner of life makes a great difference in the legitimate *necessities* of different persons; as in general society one of liberal antecedents justly needs some things which others would not enjoy or even use, if they had them furnished. The fact of disease offers to my mind no good reason for reducing the two to identical surroundings, especially when the class with the greater wants may be able and willing to bear any burden which the supply of such wants entails. . . .

"The resources depended on to meet so great a diversity of individual conditions ought, in justice, to possess great flexibility, and embrace a great range of possible changes. While this principle applies to all agencies entering into care and treatment, it has special force as applied to the question of building. A mistake or a deficiency in this direction is important in proportion to the difficulty of its correction. . . . Even though the exceptions are many, much is gained by adherence, as far as possible, to the ordinary forms and methods of living followed in the society of the sane. In proportion as this can be done, will residence at an asylum, for treatment or needed care, be relieved of the unjust prejudices which have existed against it. . . . More and more, each year, general routine methods are giving place to individual care and treatment, those more reliable have larger latitude, and self-dependence is trusted to the outer limit consistent with safety and a prudent regard to the liabilities in the case. It is easy to see how much more readily and effectively such a

principle can be carried into practice with the help of properly adjusted buildings than in those so monotonous in construction as to enforce a disregard of the nicer differences in personal character and symptoms which any considerable number of cases is sure to present."

Considering the large sums of money that have recently been spent in insane asylums and the fact that popular governments are apt to oscillate between periods of extravagance and of parsimony, especially with the aspect more or less of political expediency which the matter assumes, we cannot expect, and indeed we could hardly be justified in advising, such an entire reversal of our hospital system at once as would involve great expense. At the same time, the State of Massachusetts is liberal and intelligent and will, I think, in time, stand abreast, if not in advance, of other countries, in the humane care of the chronic insane and in the skillful treatment of those who are susceptible of cure or marked improvement. We should at least direct our efforts now to such an ultimate result.

It seems to me that in the not far future some of the harmless insane and of the acutely ill who are now sent to asylums will be otherwise cared for, and that a certain number will remain in the hospital a shorter time than is now the custom. I doubt whether custody in an almshouse will prove satisfactory to our people for a very considerable portion of the insane; and I am quite sure that we shall never find in Massachusetts many responsible families who will take care of the harmless insane in their own homes at a low enough rate to make the plan a prominent feature in our methods, as it is in Scotland and Belgium. Still, the question of responsibility of criminals will be more carefully considered as insanity is better known; and more of the dangerous insane, the vast majority of whom have been considered by the community sane or at least harmless until the committal of their crime, will be recognized to be such early enough to prevent their horrible deeds. There is also no reason to suppose that there will not be an actual increase, from year to year, in the number of our insane; and insanity is sure to be more and more held to be purely a disease, needing treatment constantly, occasionally, or rarely, but always supervision by medical men. As it will not be long, therefore, before we shall be compelled to enlarge our present hospitals or to build others, it is in the highest degree important that the State should proceed wisely, so as to secure, as of prime necessity, a better classification of our patients than we can now attempt.

First of all, provision is needed for such of the criminal insane as cannot properly be kept in prisons without manifest injustice, or retained in the asylums without seriously interfering with the management that is best suited to such institutions. They do not by any means include all the insane who have committed or attempted crimes, and could, for many years at least, be suitably cared for in the Essex County Asylum, which is discreditable to us as a place of retention for the ordinary insane, and which might be easily adapted to the wants of as many irresponsible criminals as should be kept in custody by themselves. It is unwise to place them all in one of our present hospitals for the insane, and our practice of scattering them about in several institutions seriously disorders the organization and management of them all; for the treatment in any particular ward is chiefly governed by its worst cases; and the attempt to care for dangerous criminals and others upon one method almost always results both in unnee-

essary and harmful restrictions for the one class and in a hazardous amount of liberty to the other. By getting rid of those for whom we are responsible to the courts and the community for safe keeping alone, we shall be immensely better off in our opportunities for intelligent classification of those that are left. The lunatics of the criminal class, as distinguished from those of previously good character who have committed crime by virtue of their insanity, should remain for the most part in special wards or cells in the prisons, at least until the expiration of their sentence. At the present time there are fifteen criminal insane in the Northampton Hospital; four at the asylum and sixty at the hospital in Worcester; twenty-eight at Taunton, and fifteen at Danvers, one hundred and twenty-two in all, of whom perhaps one half properly belong elsewhere, either for safer keeping or for reasons of better classification and management.

The next step should be to remove idiots to places better suited to their needs. After that, one of the hospitals might be set apart for epileptics, paralytics, and demented, while the others became gradually abodes for the chronic insane, who could at last be classified in a way to give much better results than we now get; for under our present arrangements no one of our existing hospitals can be readily adapted to the cure of acute insanity. For that purpose a new institution should be built with all the appliances of a hospital proper, embodying all the latest improvements in form and construction, to accommodate not more than two hundred patients. This need not cost over \$400,000, and should be self-supporting. Another would soon be required, which might be twice as expensive, but where the cost per patient would not exceed eight to ten dollars per week, for those who choose to pay for better accommodations.

I fully believe that some such changes as these are demanded by our most intelligent people, and that they will sooner or later come about. The proper treatment of mental disease is expensive and requires a liberal staff of physicians and attendants, as well as a full diet and ample resources of various kinds. The custody of the chronic insane is not nearly so costly and does not involve the necessity of so many and so skilled attendants. The two functions can never be fitly performed together. Even the constant presence of several hundred incurables in the various stages of loss of mental capacity is enough to take away from most of the curable cases very many of their chances of recovery. If we meet in our wards hopeless wrecks of once fine minds, if we find there the extremity of human wretchedness and the deepest depth of filth in mind and body, the supreme control of all that is evil in our nature, the worst antitypes of all the virtues, on the other hand nowhere else do we see such desperate struggles for the mastery of the worst passions or the better impulses, nowhere else such fearful efforts against such tremendous odds to hold back the mind which is felt to be slowly yielding in the unequal fight. Nowhere else, too, are developed finer sympathy, more beautiful unselfishness, sweeter charity, or more heroic resignation where no hope in life remains but for death.

The State has undertaken the charge of these three thousand people, shut up behind these locks and barred windows; it cannot evade the duty of seeing that their confinement is made the least rigorous possible, and that each one has not his chances of cure lessened by the fact that he has lost the power of directing his own treatment. It will take a long time to bring about such

changes as I have suggested; perhaps they will not come within our lives. In the mean time there are other things which we can do.

As soon as Harvard has the courage to add a fourth year to its medical course and the other colleges reach the position which Harvard will then have left behind, the general standard of the medical profession will be raised; and with that upward step the medical staff of our insane asylums will go forward also. This movement we can assist by appointing clinical clerks or medical house officers from the third and fourth year students,—more each year as there are more desirable applicants for the position,—and by giving after a few years the vacant situations in our medical staff only to those who have had such experience. Our assistant physicians and superintendents should be chosen with great care and then must possess our confidence. If they should fail in their duty let us turn them out at once, and let us hope that the governor will do the same to us when he feels that we do not accomplish all that we ought. Above all things, whatever may be said by the faultfinders that we shall always have with us, let there be no distrust of our officers on our part and none of us on the part of the State, as we mean that there shall be no grounds of that distrust which is so fatal to the best work.

The privilege of seeing proper friends or relatives and of writing must be subject to some restriction of course, but our difficulty is to get the friends to visit and send letters often enough, and to stimulate the patients to communicate with them. Each patient should have an opportunity to see at least one trustee as often as once a week. An expert lunacy commission, or commissioner, is also needed to represent the State, assist the hospitals in their work, and give confidence to the public. A board of consulting physicians can be of great service in bringing to bear upon us their judgment and criticisms from an entirely impartial point of view, in suggesting general methods of treatment, and in giving advice in those special branches of practice in which they are skilled. When the first insane asylum in New England was opened for patients there arose a question as to the organization of the medical staff, whether the physician should be a visitor, as at Philadelphia and in general hospitals, or a resident superintendent. The latter method was wisely chosen. Visiting physicians have been tried in England and Germany without success, and after Rush's death a resident medical superintendent was appointed in his place in Philadelphia. It would be impracticable for a visiting staff to follow the condition of insane patients from day to day so closely as to be able to direct their treatment if our hospitals were near large cities, while with their present situations it would be simply impossible.

For efficient service we should have, beside the medical superintendent, at least one physician to every two hundred patients, and one medical house officer to every three hundred, but not less than two assistant physicians and two house officers in each hospital. The fallacy has often been published that if a superintendent gave ten hours each day to visiting patients each one would have from one to two minutes of his time. The absurdity of the calculation lies in the fact that a very large proportion of the insane in asylums need only a safe boarding-house, with as much amusement and employment and as little restraint as is possible, and that each day comparatively few require any more from the doctors in charge than the task of know-

ing that assistant physicians and attendants do their duty.

The attendants are not less important than the physicians to the successful administration of an insane asylum. They require firmness, patience, kindness, tact, experience, and very exceptional self-control. They have every variety of duty to perform from being companions to ladies to acting as scrub-women for menials. They must be nurses, housekeepers, companions, and servants. They are expected to practice all the Christian virtues under circumstances that have sorely tried the tempers or ruined the happiness of a hundred families. That there is occasional harshness towards patients under exceptional provocation we all know, but as a rule much less, I feel sure, in our hospitals than in their own homes at the hands of their own relatives, who often insist that they are simply "ugly." If anything, we are unjust rather to our attendants than to the insane in carefully hearing complaints and in discharging those that do not under exasperating trials show even much more forbearance than perhaps most of us could exhibit. Indeed, careful investigation too often shows that the self-willed, bad-tempered patients, from whom most of the charges of harshness come, are the most abusive of attendants, and only carry out to a less degree in the hospital the same systematic brutality that they practiced upon their wives or husbands or mothers or sisters when at home with all their evil passions let loose. We and the doctors are comparatively a short time in direct contact with the insane; the attendants are their constant companions, pounded and abused by day, kept awake at night, and lied about all the time. I am amazed that we can secure as excellent service as we do. While we should aim at the highest possible standard of excellence, we should remember that we have our duties towards our attendants. For their good and for our patients' sake we must have at least a third more than our present staff wherever many acute cases are treated. We ought to give them more recreation and amusement, especially frequent opportunities for entire relaxation away from their cares. Each should have one day a week off duty in the worst wards, and all would be benefited by giving up to them, every four or five days, the amusement hall for themselves and their friends, to dance and have a good time generally. The more human we make their life in the hospital the better attendants we shall get and the longer we shall keep them. If we are to materially improve the treatment of the insane this must be where we are to begin.

For reasons which I hope to be able to discuss in another place, I do not believe that we can ever adopt to its full extent the system of so little restraint and so much employment as is at present the practice in Scotland. Notwithstanding the rather hasty generalizations of some of our critics, the result of my studies in this country and of five visits in different years to Great Britain is that the average mad American, like the "nervous" American, is more difficult to manage than the European similarly diseased,—an opinion which I find pretty generally supported by competent observers. For all that, I am confident that we can very much diminish the prison appearance of our asylums, give much more liberty to our patients, remove many restrictions from their life, give them more employment and amusement, use less mechanical restraint, and bring more healthy influences to bear upon them generally. We must hasten slowly, however, in this mat-

ter, as there are many points regarding it which can be decided only by experience, and where theories and speculations are of little avail. I think that we might, and should at once, though, abandon the use of the most objectionable forms of mechanical restraint; for instance, hand cuffs, the crib, and the mulf, the former two of which are already seldom used in most of our hospitals now, and in some never. There are most serious objections, however, to the dogmatic application of the "non-restraint system;" and the extent to which it shall be adopted, like other medical prescriptions, must depend chiefly upon the resources of each hospital and the judgment of its medical superintendent.

It is unfortunate that so many of our patients are admitted under so much deception and so hurriedly that they regard the asylum as a trap in which they are caught, and from which they take every opportunity to escape, rather than as a hospital where they are sent after mature deliberation because it is a necessity that they should be taken care of. They are sometimes committed with carelessness or haste, or upon very incomplete evidence of insanity, and are declared dangerous and sent to the most excited wards, which certainly does not improve their condition when they are quiet and harmless. I sometimes think it would be well for us to pass an order that every new patient should be placed in one of the quiet wards long enough for his condition to be thoroughly understood, and never to be sent to any ward until after a careful medical examination at the hospital.

With all the theoretical objections to our hospitals they must be used as safer places, and for the majority of cases as better places, for treatment than any others attainable. We can diminish their objectionable features, add to their advantages, and possibly increase the chances for recovery in them. If there were to be one rule of the thumb it should be, *multiply healthy influences to the last degree possible; remove, separate, destroy from each and all, as far as may be, all that is morbid, by better classification and every other means practicable.* The most we can do each year in these respects may seem very little, but it is a little to us which is great to the inmates of our hospitals, and which in the course of time will appear great to everybody.

There are many matters of strictly medical treatment which we have not time to consider to-day. There, too, I think there can be an improvement, for which we must look chiefly to the medical officers. The chief thing for us to do is to look at the matter from a broad point of view; to remember that our duty is not simply to preserve life, but something higher, to make life, if possible, worth living; to remember that just in proportion as we take away all opportunities of self-control, self-guidance, and self-help, and remove all that is natural, cheerful, and hopeful, just so far do we stimulate the desire for self-destruction and diminish the effort and chance for improvement and recovery.

Our task is no light one; much of it, I think, can never be done to the fullest extent possible without the assistance and support of a competent, skilled lunacy commission, or commissioner, appointed by the State, for which, perhaps, we need hardly hope. We must expect misrepresentation and abuse, we must look for disappointment in many of our plans, we must make many mistakes, we must be weary waiting for the results of our labor; but the sensible part of the community will fairly appreciate our efforts, and we are not fit for our work unless our shoulders are broad

enough to bear unjust suspicion, distrust, and blame even from sources where we have a right to expect something different.

MOVABLE KIDNEYS.¹

BY D. H. HAYDEN, M. D.

ABNORMAL mobility of one or both kidneys is now generally admitted to be a not rare occurrence. The first article upon the subject that can be said to have produced any effect upon the medical profession was that by Rayer in his work on Diseases of the Kidneys, 1841. Oppolzer gave a very clear account of this anomaly in the *Wiener Medicinische Wochenschrift*, No. 43, 1856. Dr. Charles J. Hare followed with a much more exhaustive article on the subject, which appeared in the *London Medical Times and Gazette* of January 2, 1858. Numerous other authors have contributed papers and clinical lectures upon this affection (notably Rollet, Hensch, Trousseau, Ebstein), and a large number of cases have been reported in various journals and in the records of medical societies. Many prominent members of the medical profession in England, however, had continued to be skeptical as to the existence of such an affection; and as recently as 1876 the Pathological Society of London, in view of the numerous clinical facts and autopsies that were collecting in the various medical journals, appointed a committee "to inquire into the subject of movable and displaced kidneys." The committee consisted of Drs. Hare, Bristowe, Wilks, John Williams, and J. Wickham Legg. In their report they stated that the evidence showed mobility of the kidneys to be by no means infrequently met with. From the numerous post-mortem observations collected one of two conditions was shown to prevail: either the kidney lies loose from attachment to the peritonæum so as to admit of being moved a certain extent in any direction, or else it is completely invested by peritonæum which passes over it to form a meso-nephron of greater or less length. According to Oppolzer the affection is usually congenital, as shown by the lengthened condition of the vessels; and rapid emaciation occurring in persons usually fat, concussion of the body, as in rough traveling, constipation, etc., probably contribute to its production. In nearly all cases where there has been an autopsy the kidney has been found healthy, but with a deficiency in the cushion of fat and a lengthening of the renal vessels, thus verifying the statements of Oppolzer in this regard. The united experience of all observers shows also that (1) this affection is much more common among females, and that (2) the right kidney is much oftener affected than the left. According to Professor Bartels, of Kiel, movable kidneys among the working women classes are often due to their habit of wearing tight waist strings to hold up their heavy skirts. He has also met with cases amongst persons in the military service and amongst workmen, due to a similar constriction of the waist, among the former by tight sword belts, and by the too tight straps worn by the latter to hold up the pantaloons. Ebstein² and Hertzka³ attribute the most frequent cause to repeated pregnancies. The following objections have been offered to this latter theory:—

(1.) Why a so minimum number of women who have borne children suffer with this affection.

(2.) Why, on the other hand, it is so often found in women who have never borne children.

(3.) Why the left kidney so generally as a rule escapes.

(4.) Why other heavier abdominal organs, whose attachments would more easily allow mobility, should not become dislocated rather than the kidneys.

In a large proportion of cases movable kidneys cause no symptoms, and the tumor is accidentally discovered, often by the patient. According to Oppolzer, in addition to sensitiveness caused by firm pressure upon the kidney in any direction, the patients complain spontaneously of a sense of pressure and a dragging, especially when standing, performing active movements, during defecation, etc. In all the cases seen by him the urine has been normal. When pains are present they are almost always relieved, and not infrequently removed, by the recumbent position.

The tumor is generally felt in the right abdomen deep under the liver, having a more or less ovoid form, is smooth and of the consistency of a kidney. It is extremely rare that the hilus can be made out and only in the thinnest subjects. The tumor can be moved within certain limits, sometimes as far as the navel, and even into the iliac fossa; and can be made to disappear upwards and backwards into the renal region. A flattening or depression can sometimes be made out in the posterior lumbar region when the kidney is displaced downwards. Rayer mentions one or two such cases. Trousseau states that by skillful palpation it is discoverable that the renal region on that side does not contain a kidney; and percussion is sometimes found to be more resonant than on the opposite side, giving place to the normal dullness when the kidney is replaced.

The degree of mobility of the kidney varies very much, amounting at times to but a slight departure from the usual tolerably fixed condition. For the examination of these cases Dr. Hare recommends the following method:—

The patient to be placed on the back, inclining slightly towards the side in which the tumor lies (generally the right), with head and shoulders raised, and legs slightly elevated, the observer standing or sitting upon that side of the patient, but somewhat facing the patient. The fingers of the left hand should be placed on the posterior lumbar region, immediately under the last rib, at the same time gently pressing or pushing forward that part. The ends of the fingers of the right hand should then be placed in front just below the costal cartilages and there also slight pressure should be exerted. The lower end of kidney will then be probably felt between the hands. The patient should then be told to take a long inspiration, and then to expire slowly. The observer should in the meanwhile keep his hands in the same position as before, but just at the commencement of expiration should pass the fingers of right hand rather sharply down towards the renal region and he will probably detect a much larger portion of the kidney between the hands than previously. It has been detruded downwards by action of the diaphragm.

The diagnosis of movable kidney, when accessible to palpation, is, as a rule, not difficult. In very stout people it would be often impossible, but in such persons it is said almost never to occur. Errors in diag-

¹ Read before the Boston Society for Medical Observation, May 2, 1881.

³ Wiener Med Presse, 1880, No. 48, Dislocated Kidneys.

nosis, however, have not been uncommon, and patients have been subjected to active and unavailing treatment from ignorance of the true nature of the affection. Trousseau reports cases where the abdomen has been found covered with leech bites, or the cicatrices resulting from the application of tartar emetic ointment, on the supposition that there existed peritonitis. In one case the patient had been taking for a long time iodide of potassium with the object, "fortunately unsuccessful," of producing absorption of the tumor. Dr. Rayer in his work, says: "The pains which sometimes accompany mobility of the kidney have been mistaken for nervous colic, for the phenomena of hypochondriasis, and sometimes for lumbar and sciatic neuralgia." Cruveilhier writes: "I have seen the tumor formed by displaced right kidney treated for obstruction of the liver or a morbid growth." Errors in diagnosis have been known to lead to dangerous mistakes. One case is reported in the *Lancet*, March 18, 1865, which was mistaken for an ovarian tumor, and the operation begun for its removal.

The tumors most likely to be confounded with a movable kidney are cancerous or tubercular masses of the omentum and mesentery or floating tumors in the peritoneal cavity. It would be extremely rare for these masses to have the size, shape, and smoothness of a kidney. Cachexia, too, would be present without other cause to explain it, and if the tumor had lasted any length of time any change which had taken place in its size would be a valuable diagnostic point. A movable spleen lies immediately against the parietes, and gives rise to dullness, whereas the kidney, if of normal size, would be covered by intestine unless detrued downwards and brought to the front. The spleen if found in this situation would be much larger than the kidney and less movable. The liver is never movable, and if a movable kidney were associated with an enlarged liver the margin of latter could generally be made out and the kidney found to slip beneath. An enlarged gall-bladder is sometimes very movable, but lies generally in a more oblique direction towards the left iliac fossa, its lower end is more globular and less hard on pressure, and sometimes fluctuation can be detected. It is only the distal end of the gall-bladder that is movable, the other end being attached to the liver. A tumor of the intestines would be accompanied by characteristic symptoms. A collection of feces would have a different feel and shape, and would not slip into the hypochondriac region like a movable kidney. An ovarian tumor to extend high up into the abdomen would always have a considerable transverse diameter. A mistaken diagnosis has been mostly due to the physician not bearing in mind the possibility of the existence of a movable kidney.

In an article by Dr. Mueller-Warnek,¹ assistant physician to the medical clinic of Kiel, the author states that so relatively large a number of women came for treatment to the hospital with well-marked symptoms of dilatation of the stomach, where examination showed an abnormal mobility of the right kidney, that one was forced to regard the complication as not accidental, and to admit the dependence of the one affection on the other. Professor Bartels was the first to show a causal connection between the pressure of tight waist strings upon the kidney and its mobility on the

one hand, and between the mobility of the kidney and dilatation of the stomach on the other. In confirmation of this theory the writer claims to be able to demonstrate both by cases and experiments on the dead body that the pressure exerted by these waist strings is sufficient to cause this result, all other causes having been excluded, and in two or three cases the symptoms being found to gradually develop. From a study of the topographical anatomy of this region he shows how the right kidney and the descending part of the duodenum are wedged in on all sides between solid parts save in front and below. By numerous experiments on the cadaver the furrow resulting from the constriction by tight waist strings was found to fall on the middle of the right kidney, or somewhat below the middle, whilst the thorax is in position of expiration or at rest. The effect of inspiration and of the consequent pressure upon the intra-abdominal organs under these favoring conditions is to displace the kidney, which has become or is already movable, forwards and inwards. Where the respiration is often subjected to long-continued increased action, as in many kinds of heavy work, a loosening of the kidney in its normal site is first produced, and later a dislocation takes place in the above mentioned direction. When the kidney has once become movable the pressure alone suffices to cause a compression of the duodenum against the vertebral column, which, from the absence of any mesentery, is not able to escape out of the way. The left kidney is not subjected to the same causes owing to its different anatomical relations, and thus escapes. The writer explains the fact of the greater frequency of movable kidneys among the working classes and the comparative exemption of the upper classes by the different action of the tight waist strings worn by the former from that exercised by corsets worn exclusively by the latter, the pressure of the corsets being more uniform over a large surface. The normal situation of the right kidney is not a constant one, and the furrow caused by these strings would not therefore always act upon it in the same way. Predisposing causes are also at work in certain persons, and movable kidney is often congenital. The author advances these as the reasons why some are affected and others not of those subjected to this cause, and a combination of circumstances is generally necessary. If the author's views are correct a prophylactic treatment is of great importance, and suggests itself.

Edema of the lower extremities has been said to have been caused by a movable kidney, and Rayer, in his work, reports one case where obliteration of the vena cava was due to it. In all the six cases reported by Dr. Hare there was noted an unusually strong abdominal pulsation.

Now and then severe inflammatory attacks, ushered in by chilliness and accompanied by intense pain, lasting a week or so, have been observed to occur in connection with movable kidney, palpation revealing a smooth and very sensitive tumor, which rapidly becomes too tender to admit of any pressure, the abdomen becoming tense and hard with often an increased area of dullness, due to the considerable exudation which has taken place. Dietl has described these paroxysms as "evidences of incarceration." The most probable cause is an irritation of the surrounding connective tissue and peritonæum consequent upon some sudden change of position of the kidney. The explanation by Gilewsky that acute hydronephrosis and pye-

¹ Unnatural Mobility of the Right Kidney and its Connection with Dilatation of the Stomach, *Berliner Klinische Wochenschrift*, No. 40, 1877.

litis have been produced in these cases by a twisting of the kidney on its own axis and a consequent compression of the ureter is not correct, as some autopsies have shown no such state of things. Pyelitis, too, is not always found where the signs of incarceration have been present, and often exists where these signs are absent.

With regard to the proper treatment of movable kidney but little requires to be said. Confinement of the bowels and the consequent straining at stools are to be avoided. Pain will generally be relieved by the horizontal posture. Elastic abdominal bands are recommended by some, though according to Oppolzer they do no good. A correct diagnosis is of chief importance, "which," as Ebstein truly remarks, "often acts as a complete remedy."

The following cases were met with in the out-patient department of the Massachusetts General Hospital. The patients were all women. They had all discovered the tumor themselves. In all but one of the cases tumor was in the right side. The notes, which were taken at the time, are very imperfect, and the patients were seen but once.

CASE I. December 29, 1876. L. F., aged thirty-seven, married, born in Maine, resides in Cambridge. Eight months' duration. There is a solid body, size of a kidney, felt, when patient sits up, to the right of umbilicus, movable in different directions, particularly upwards. Micturition frequent and painful.

CASE II. June 8, 1876. M. L., aged forty, born in Ireland, resides in Gloucester. There is a solid and movable body, below border of left ribs, apparently unconnected with the spleen, about the size of a fist. Patient has been aware of its existence five months. At times it is painful and sore on pressure.

CASE III. December, 1876. A. P., aged forty-three, born in Ireland, resident of Lawrence. Four years' duration. Patient is subject to renal colic. In right abdomen, below the border of the ribs, there is a movable body suggestive of a kidney. Patient is obliged to pass her water every half hour day and night. There is constant uneasiness in hypogastrium and back. When patient lies on her left side the tumor presents, and can be grasped through the parietes. Percussion is found to be resonant over renal region of this side when compared with opposite side. If the patient is then held in the horizontal position the tumor disappears and can no longer be felt, and percussion in the right renal region becomes completely dull. This change in percussion with change of position was unvarying as often as the experiment was repeated, and was easily demonstrable to others who saw the case.

CASE IV. July 21, 1875. E. McC., aged thirty-two, married, born in Ireland, resident of Hopkinton, Massachusetts. On deep inspiration a solid body about the size of a kidney is made to appear, and can be grasped in right abdomen. The tumor can be moved in a downward direction, and then easily pushed upwards and made to disappear behind. Patient has had this tumor as long as she can remember, and there has never been any pain, soreness, or other symptoms connected with it.

CASE V. March 24, 1875. A. B., aged forty-four, married, born in Maine, resides in Gloucester. There is a tumor felt to the right of umbilicus, movable, which can be pushed upwards and made to disappear posteriorly. Tumor disappears and can no longer be

felt when patient lies on her back. Patient describes symptoms as of something "dragging" in right renal region, and complains of an occasional pain to right of navel.

CASE VI. April 18, 1881. The following case has come under observation since the above paper was written. H. A., aged thirty-seven, married, and has had three children, last confinement being three years ago. Five years ago patient had an attack of what she describes as not being a real pain, but the sensations being like a "burning sore" and "pressing" in right hypochondrium, with some swelling, requiring medical relief. Two years ago she had a similar attack, and between then and the following August (1879), perhaps as often as ten times, similar attacks. She has had none since then, and has been perfectly well, save that three months ago she had a miscarriage. Five months ago she discovered the presence of a tumor, which frightened her greatly, and on account of which she consulted a physician, "who," she says, "told her that it was a lump which had fallen down from the liver." A second physician consulted thought the tumor to be a growth from the walls of the stomach, and prescribed a course of internal treatment and the application externally of some form of iodine, as the character of the stains upon the skin showed.

Examination, April 18, 1881. Patient's general condition appears good. Is moderately stout. Abdominal walls considerably relaxed and flaccid. While lying on her back, inclined towards the right, on deep inspiration a movable, smooth, solid body of ovoid shape, size of a kidney, can be felt to the right of and a little above the level of the navel. It can be grasped and pushed upwards and backwards out of reach, its rounded end slipping through the fingers like a "greased egg," as Mr. Taylor, one of my assistants, aptly described it. There is quite a depression formed when the plessimeter is applied to the renal region of this side, and the percussion sound here is fuller and more resonant than on opposite side. When patient lies on her back, inclined towards the left, the tumor can no longer be felt in front as before, the resonance disappears posteriorly, and percussion gives an equally dull sound with that of the opposite side. There is some sensitiveness on firm pressure. With the exception of a pain in the back, which she has had for the past two weeks, now about gone, patient has had no symptoms of any kind. This case illustrates very well the importance of a correct diagnosis, both from thus being able to relieve the patient's anxiety and mental suffering, as well as to prevent useless and unnecessary treatment.

A CASE OF PROLONGED INTESTINAL OBSTRUCTION.¹

BY F. W. DRAPER, M. D.

THE patient was a man, aged thirty-three years. His occupation as a teacher led him into sedentary and rather indolent habits of life. For many years constipation had been the rule with him. In 1875 he had an attack which confined him to his bed for several weeks, and which he describes as "inflammation of the bowels." After this illness he was the subject of recurrent attacks of more or less prolonged

¹ Read before the Boston Society for Medical Observation, May 2, 1881.

and obstinate constipation, attended with a distressing accumulation of flatus; this latter condition of flatulence became especially annoying to him, and was the source of the greatest discomfort and anxiety. On one occasion, in 1876, he went ten days without a fecal dejection; this was the longest period of intestinal inaction till the present attack.

During the years 1878 and 1879 I saw him at irregular intervals, and prescribed for the relief of his abdominal symptoms. Suspecting that in some way, not clear on physical examination, the recurrent attacks might be due to the presence of inflammatory products, the consequence of his illness in 1875, I withheld active cathartics, and used in the treatment the milder laxatives (podophyllin, compound extract of colocynth, and the like) in combination with belladonna and nuxvomica. After the use of these remedies, with turpentine stupes and other counter-irritants to the abdomen, the bowels would presently resume their natural function, and an interval of entire comfort would follow.

In the spring of 1879 a somewhat prolonged period of constipation and flatulency, attended with occasional vomiting and some pain, though yielding to the treatment previously effectual, left the patient in an unusually prostrate condition. He went into the country and spent the summer, returning to his post in the autumn in excellent health. Through the winter and until the beginning of the present, his last, attack, he was comparatively free from discomfort, and if he had any trouble with his intestines it was not severe enough to require special treatment.

June 28, 1880, after indulgence in iced water, he was attacked with slight vomiting, distention of the abdomen, and moderate pain. The matter vomited was of a bilious character.

I saw him for the first time on the first day of July. He was then much distressed by the great accumulation of gas in his intestines; the abdomen was uniformly distended and tympanitic, and careful palpation and percussion detected no region presenting exceptional signs with relation to the rest. Vomiting had ceased spontaneously. There was the customary constipation; there had been no dejection for three days. There was no tenderness of the abdomen. In all respects except as regards the constipation and tympanites, the patient was comfortable. There was no fever; the pulse was normal in strength, ranging from 80 to 90, the tongue was moist and clean. The appetite was lessened but the stomach retained and digested liquid diet satisfactorily.

Without following the course of the attack from day to day, the general remark may be made that there was no material change in the condition during *twenty-one days*, for which period the intestines were continuously obstructed, and the gaseous distention persisted. In the afternoon of the twenty-first day flatus escaped by the anus, and presently a dejection of scybalous feces followed. The next morning a normal stool was voided, and thereafter for nine days the patient, though weak, appeared to be in good health and spirits; his greatly-distended abdomen resumed its natural appearance, and there was a daily defecation. He rode out twice during the nine days, and appeared fully convalescent.

During this prolonged period of twenty-one days of intestinal inaction the patient took nourishment by the mouth in small amount at short intervals; he was

afraid to take liquids freely lest they should increase the gaseous accumulation; there was no nausea or vomiting.

The subject of the treatment can be dismissed in a few words. At the outset the remedies previously found effective were employed, namely, laxatives, turpentine to the abdomen, and stimulating enemata. On the ninth day half an ounce of sulphate of magnesia was given in a dilute solution; it produced no effect beyond slightly increasing the patient's misery. Belladonna was now tried till the physiological effects gave warning to desist.

On the fourteenth day, with the concurrence of Dr. O. W. Doe, who saw the patient in consultation, the aspirator was used to withdraw the gas; four punctures were made into the most prominent points of the abdomen; three of the operations (performed as aspiration of fluids is performed) were successful in withdrawing a large quantity of fetid gas; in the fourth puncture the needle passed between two folds of intestines. The smallest needle was used. There was no ill-effect in consequence of this operation. The abdominal distention was greatly relieved, and only a little local tenderness marked the places of puncture.

On the fifteenth and sixteenth days Dr. W. C. B. Fitch saw the patient with me. In accordance with his advice the use of belladonna was resumed. The drug was given in the form of the extract in half-grain doses every hour till delusions of vision and other marked physiological effects were developed; three grains were thus taken daily for six days.

Meanwhile large enemata of simple warm water were administered with the fountain syringe, the patient being in the knee-and-elbow position; he repeatedly took three pints of the enema, and on several occasions received as much as two quarts, the direction being that he should have as much as he could bear. These enemata were given once in six hours for four days; their use being attended with some irritation of the anus at the end of that time they were given once a day only till the twenty-first day, when the obstruction was relieved and all treatment was remitted.

The conclusion of the case remains to be told. As has been remarked, upon the relief of the obstruction, all the functions were restored and the patient enjoyed a comfortable convalescence during nine days; the appetite returned, the vigor of mind and body were revived and although the patient was cautioned to take advantage of continued rest, and to regulate his diet with some care, he was ambitious to return to his usual duties. In the afternoon of the ninth day he was attacked with moderate pain in the abdomen, attended with vomiting of a bilious, viscid fluid; there had been a dejection earlier in the day.

Next morning the pain continued though the vomiting was relieved; there was a natural dejection in the morning of this day. Accumulation of flatus developed in the usual way. The patient noticed that in this attack the pain was much more severe than in former seizures and there was more tenderness than before; he did not localize these in one part of the abdomen more than in another.

At the end of the second day it was evident that the patient was sinking under the persistent and severe pain; morphia had been used freely and with benefit, mitigating the abdominal distress, but not producing narcosis. Hot fomentations were also employed. Stimulants were now added to the treatment. There

was a small defecation after an enema in the morning of this day.

During the third day, the symptoms increased in severity; the abdomen was fully distended; the pain persisted; the skin was cold; the pulse was 160 and thready. The aspirator was used again with but slight temporary effect. The respiration was compromised but slightly. Death occurred seventy-two hours after the onset of the attack.

An autopsy, confined by request to the abdomen, was made thirty-two hours after death. The abdominal walls were distended to their utmost; when the usual longitudinal section was made the intestines escaped through the incision in huge convolutions. The entire length of the small intestine and the ascending and transverse portions of the colon were fully loaded with mingled liquid and gaseous contents. The peritoneum was everywhere injected, and the vessels of the omentum were especially engorged. In the dependent portions of the abdomen there was an effusion of dark-red, thin fluid, amounting, by estimate, to eight fluid ounces. The color of the small intestine was a dark purple; its diameter was that of a large orange; its contents consisted of dark brown, fetid liquid feces. The distended large intestine was of a pale color; its diameter was six inches and its contents semi-solid feces. Search was made for the points of puncture by the aspirator needle, but no remnant of that operation was found. There was no agglutination of the intestinal folds or other indication of peritonitis, beyond the intense general hyperemia and the fluid exudation.

At the junction of the transverse and descending portions of the colon (splenic flexure) there was a cicatricial constriction. In the concavity of this flexure the three coats of the intestine were drawn into a firm, dense mass of tissue, the puckered folds of which contraction had reduced the calibre of the gut so as scarcely to admit the tip of the little finger. Above this stenosis the intestine was dilated into a great bag or reservoir filled with semi-solid feces; below it the gut was contracted to its normal dimensions. Seen from within the intestine showed nothing remarkable at the constriction beyond the puckering of the mucous lining; on the outside (peritoneal surface), however, the stenosis was marked by a roughened, elevated ulceration of the size of a silver quarter-dollar. A fold of the jejunum was attached by loose adhesion of its free border to this ulcer, and its peritoneal coat presented a corresponding, though more superficial, loss of tissue. The situation and relations of the constriction were such that it could easily be plugged by a fecal mass of slight consistency.

Upon the surface of the large intestine, just above the ulceration, was a minute perforation which hardly admitted the head of a probe, and through this small opening enough fecal matter had probably escaped to develop the peritonitis which destroyed the patient.

—The medical faculty of the University of Berlin proposes the following subjects for prizes in 1882: (1.) An experimental examination of the action of nerve-stretching on the peripheral nerves and on the central organs of the nervous system, with reference to the researches of Brown-Séquard. (2.) A historical and experimental criticism of the different methods of suture of the intestines.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M. D.

THE STRIATION OF MUSCULAR FIBRE.

Two papers worthy of mention have recently been added to the literature of this vexed question. One by Wagener¹ describes some curious appearances which may be observed on the muscles of the thorax of a fly. It is to be remembered that the fibres of these muscles are very much smaller than those of the legs, and that perhaps each of the former represents a "muscle column" by the union of several of which the larger muscles are composed. First catch the fly, then divide it longitudinally with a pair of scissors, and take a little muscle from the thorax. Put it quickly into a drop of water on the slide, spread it out a little, and cover it in. A power of three hundred diameters will show cross stripes on some fibres and none on others. Place one of the latter in the field so as not to mistake it, and, according to Wagener, in a short time bright cross lines will appear at once throughout the fibre. They presently become clearer, and while the observer is wondering whether he has not mistaken the fibre the same phenomenon will recur by the appearance of a new set of lines, each of which will be midway between two of the former ones. The latter set will gradually become as clear as those that appeared first. The writer of this report has verified the main points of these observations. He would not dare to assert that he has ever seen the stripes suddenly appear, but he is sure that he has seen them in fibres in which he had not seen them a few minutes before, and also that the stripes became more numerous as the observation was prolonged.

Wagener believes, however, that before this other changes had taken place which require very high powers. With these he sees a very fine cross striping appear very soon after the preparation is made. This is soon followed by a coarser one, and then occur the changes described above. The writer, at the time of preparing this report, did not have access to a lens capable of showing these appearances. He would state, however, the very important fact with regard to the stripes which he could see, and which Wagener calls light ones, namely, that their lightness or darkness is entirely a matter depending on the arrangement of the light and on the focus. It is to be regretted that Wagener attaches much importance to polarization, and uses the terms "isotropic" and "anisotropic." We cannot doubt that the polariscope has cut off a great deal more light from this question than it has thrown upon it. The most diverse views are held as to the optical qualities of different parts of the fibre, so that we are often more than a little puzzled to know which disk a writer means when he alludes to the double or single refracting substance. Ranvier, indeed, maintains that the optical qualities of a given part of the fibre vary with the tension to which it is subjected.

According to Wagener, the anisotropic (light) stripes have the property of expanding and contracting, which Engelmann believes is due to the absorption and rejection of water respectively. Moreover, these light bands can join one another to form larger ones, the

¹ Ueber die Entstehung der Querstreifen auf den Muskeln, etc. Archiv für Anatomie und Entwicklungsgeschichte, 1880, Heft 4 and 5.

intervening black bands of course disappearing, and this process may be repeated. He believes firmly in the fibrillar structure of muscle.

The following application of Wagener's theory deserves notice, though it is our purpose to confine ourselves pretty closely to the cause of the striation. "The appearance of the borders of the so-called heart cells depends on the existence of smallest anisotropic bands, and on their property of uniting with their neighbors; for these borders consist only of rows of enlarged anisotropic bands which may appear and vanish under the observer's eye."

Though ready to admit the correctness of many of Wagener's observations, we feel confused rather than enlightened by his paper. If we did not know that stripes exist in the living fibre we should infer from this method of demonstration that they are post-mortem changes. We would ask, moreover, what becomes of the fine, dark (isotropic) stripes between neighboring light ones when the latter unite.

A very interesting paper by Mr. Hayercraft¹ presents a new theory of the cause of the stripes. We are not convinced that the explanation is complete, or rather we are very sure it is not, but we believe, as we have for a long time taught, that many of the appearances and changes of voluntary muscular fibre are simply optical effects. Mr. Hayercraft points out some of the changes due to alteration of the focus, of the direction of the light, etc., and comes to the conclusion that the stripes depend on the shape of the fibre. This he believes resembles the legs of some old-fashioned chairs that appear to consist of a series of balls placed one above another. Supposing this to be the shape of a fibre composed of a homogeneous transparent substance, it is evident, first, that very different appearances will occur on changing the focus of the microscope (from, for instance, that of the top of the ridges to that of the bottom of the depressions), and, second, that there can be no focus which can be called the correct one *par excellence*. Mr. Hayercraft has made a model by dropping a drop or thread of Canada balsam on a slide and indenting it with the milled head of a fine screw. A low power shows stripes which correspond with the surface impressions, and, moreover, are reversed by a change of focus. Another experiment is best given in the author's own words: "The most beautiful and convincing object to study in this connection is a scale of the *Lepisma*. They are oval in shape, transparent, and single refractile throughout, and beautifully ribbed in their length, these ribbings or groovings being indeed so fine that a power of at least five hundred diameters will be required to make out those points to be here described. You would think on looking at one of these scales that a piece of muscle was flattened out before you on the field; no rough balsam model, but a perfect illustration taken from the back of a tiny insect.

"The appearances it is needless to describe, for they are, almost to the minutest detail, those of muscular fibre. The bright and dark stripe interchanging with every alteration of focus, Hensen's stripe and Dobie's line (Krause's membrane) are all to be seen."

The fact that some staining agents appear to act on certain stripes more than on others may be brought forward as an argument that the fibre is composed of dif-

ferent substances; but Mr. Hayercraft replies that in such stained specimens the effect is changed by changing the focus, and, moreover, that a similar effect is produced by placing a piece of colored glass between the stage and the mirror.

It should be stated that Mr. Hayercraft also believes in the fibrillar structure of muscle, and holds that each fibril is shaped in the same way as the fibre. These are held together by a cementing substance, and, moreover, there possibly may be very delicate transverse membranes at the narrow black lines which run to the depressions between the scallops. Now, as the author recognizes, it is essential to the validity of his theory that voluntary muscular fibre when striped should have a scalloped edge, and that when the edge is smooth there should be no stripes. Some specimens of the latter kind which he has seen strengthen his confidence. In an *addendum* he says: "An assertion has been lately made which if true would be entirely fatal to my views. It was that in the fresh condition the fibres are cross striped, but at the same time their borders are quite smooth. That this is erroneous is easy of demonstration with any fresh fibre, but especially with that of an insect. It is true that often from the manipulation, or their own contraction, they are twisted, when the convex border will on a careless inspection appear as a distinct line. The stripes at this point are not at all distinctly seen, but yet can always be made out, as well as the crenulated border."

This undoubtedly is the question. The writer in verifying Wagener's observations, mentioned above, on the small fibres from the fly's thorax (very different from those of the legs) paid particular attention to this point, and was unable to see the scallops with a Harnack 9 immersion with either central or oblique light. They are not to be seen in Wagener's drawings. The writer's former observations on the muscles of the leg of the small water beetle (*Gyrinus*) convinced him that stripes could be seen in fibres with straight edges, though they undoubtedly become much more marked as the scallops appear in the edges of the contracting muscle. In short, though Mr. Hayercraft's theory may account for many of the appearances of muscular fibre, it will not do to believe that striation depends solely on its form till it is proved beyond question that the edge of a striped fibre always presents a series of bulgings.

THE CIRCULATION IN THE HEART.²

While making a series of injections of the vessels of the heart, Dr. Langer was struck by the regularity with which the injection was found in the ventricles. He satisfied himself by compressing the larger veins opening into the right auricle, by plugging both auricles, and by attending to the position of the heart during injection, that the fluid did not run down from the auricles, and he also assured himself that no extravasations occurred. Consequently it was only through the openings of minute veins that the fluid could have reached the ventricles. These are perfectly analogous to the *foramina Thebesii* which exist in both auricles, though they are, I think, usually described only in the right one. It would be more correct to say that these openings are analogous to some of these foramina, as others are merely blind pouches. Indeed, Cruveilhier,

¹ Upon the Cause of the Striation of Voluntary Muscular Tissue. By J. H. Hayercraft, M. B., A. R. S. E. Quarterly Journal of Microscopical Science, April, 1881.

² Die Foramina Thebesii im Herzen des Menschen. Dr. Ludwig Langer, Sitzungsberichte der Akademie der Wissenschaften, Wien, 1880, Band LXXXII. Heft 1 and 2.

Theile, and Luschka held that the latter form is the only one. There is no mention in modern literature of such openings into the ventricles, but Langer made the discovery, a more curious one than that of the openings themselves, that there had been a lively discussion concerning them in the early part of the eighteenth century. They were described by Thebesius in an inaugural dissertation in 1708, and also by Viensens in 1715. The observations were confirmed by Winslow and others. Laucisius wrote, in 1739, "*Mihi non amplius fuerit dubitandum, quin lateat intimum commercium venarum coronarium cum utroque cordis ventriculo.*" Other anatomists, among whom was Haller, disputed the matter, and it would seem that the latter side carried the day, for these openings into the ventricles have been forgotten.

Dr. Langer demonstrated these openings in various ways. Air or fluid injected into a cardiac vein appeared on the inside of the ventricles. This method was reversed by placing a tube over one of the pits in the ventricle, and throwing the injection in the other direction. It is to be remembered that there are a great many little blind pouches, which perhaps accounts for the diversity of the views. The minute venous openings, *foramina Thebesii*, are found in all the four cavities. In the left ventricle they are most numerous in the large papillary muscles, in the right ventricle near the conus arteriosus. These little veins have no direct communication with the larger veins of the heart, but may be compared to the intra-lobular veins of the liver, that is to say, each carries off the blood from a small district. They can, therefore, be demonstrated only by a good capillary injection.

THE UPPER AND LOWER BOUNDARIES OF THE PLEURA.¹

Dr. Ad. Pansch publishes the results of many observations on this question. There is a good deal of diversity and vagueness in the statements of authors on the first point. We, however, will skip these and come directly to the views of our author, namely, that the upper border of the pleura, which closely covers the top of the lung, usually corresponds with the anterior edge of the neck of the first rib. This has the merit of giving us a fixed point for a guide, which none of those in the front of the chest can be called. The anterior end of the first rib may vary decidedly in its relation to the vertebral column and the clavicle may vary still more. The great objection to this guide is the difficulty or impossibility of finding it in the living. Pansch gives the vertical height of the top of the pleura above the anterior end of the first rib as 3.5 cm. It varies from 2.5 to 5.5 cm. He does not find any regular difference between the right and the left sides. It is more common for the lungs to pass the usual point than not to reach it. The author implies that the clinical statements that the lung rises from three to five cm. above the sternal end of the clavicle cannot be strictly correct. It may be possible to obtain pulmonary resonance on percussion for this distance from the clavicle, but it must be remembered that this line slants upwards and backwards instead of being vertical.

The lower border of the pleural sac, unlike the upper, is in no definite relation to the lower border of the lung, and indeed is always beneath it. According to Pansch the lower border of the pleura usually is op-

posite the middle of the vertebral border of the twelfth rib and extends outwards at first horizontally and then gradually rising till it passed upwards at the front of the thorax opposite the junction of the seventh rib with its cartilage. The pleura is sometimes found to extend much lower, even as far as the transverse process of the first lumbar vertebra. This of course may be of considerable surgical importance.

THE FISSURES OF THE LUNG.²

Dr. J. L. Cilley, of Cincinnati, points out that the main fissure of the lungs is incorrectly described in English works on anatomy. In the last edition of Quain it is said to extend downwards and forwards to the anterior edge. Dr. Cilley continues: "The forty-four cases of the writer did not furnish a single case where the anterior edge was reached. In every case did the so-called upper lobe enter into the formation of the inferior border of the lungs. In only one instance did the fissure approach nearer than three inches to the anterior edge, and then it came within one inch." This point is correctly described in Henle's great work, but, as far as we are aware, in no work which has yet appeared in English.

Hospital Practice and Clinical Memoranda.

A CASE OF DIABETES MELLITUS; RECOVERY UNDER MORPHIA TREATMENT.

BY S. G. WEBBER, M. D., BOSTON.

THE following case, treated at the City Hospital, is of interest because of the presence of cerebral symptoms, showing the gravity of the patient's condition; also because of the speedy relief which followed the strict adherence to a diabetic diet, and the results obtained by morphia.

John C., aged forty years, painter, entered City Hospital December 11, 1880. The history he gave was that during the previous August he suddenly ceased to sweat, and the amount of urine he passed steadily increased up to five to sixteen pints daily. His skin was very dry, but not harsh. During the summer he had been several times greatly overheated. He had slight headache, with considerable dizziness; his eyesight had failed much during the previous six months. His appetite was fair; there was a sensation of heat in the stomach two or three hours after eating, frequently followed by vomiting. He had lost strength and flesh, about fifty pounds in weight. His bowels were constipated, passed urine about every one and a half hours during day and night, and was very thirsty. There was no swelling of the extremities, no cough, no cardiac symptoms.

The urine was pale, acid, 1031 specific gravity. No albumen. Much sugar. Nothing abnormal in sediment.

December 15th he had an attack of dizziness, beginning with discomfort in his stomach, then tinnitus and vertigo, followed by nausea and vomiting. He said he had had six such spells in the last six months. He had another similar attack of much less severity on the 25th.

He was put upon partial diabetic diet, and December 16th upon full diabetic diet. Being a painter, he was

¹ Archiv für Anatomie und Entwicklungsgeschichte, 1881, Heft 2 and 3.

² Contributions to Gross Anatomy, together with some Observations on Abnormalities. The Cincinnati Lancet and Clinic. February 25, 1881.

given iodide of potassium five grains three times daily, upon the possibility that there might be some affection of the floor of the fourth ventricle. If the overheating of the last summer had any aetiological effect the iodide would also have been indicated.

There were no further attacks of vertigo, and on December 28th the patient made the following statement of the improvement he had noticed: Increased appetite. Mouth much less parched and furrowed. Decrease of thirst. Great decrease of urine. Less pain in back. Some increase of strength. Better eyesight, and a clearing up of the head from the dull, dizzy, and oppressed feeling. Bowels more regular.

During the progress towards recovery he had a few periods in which disturbance of the stomach or bowels, or catching cold, caused an increase in the amount of urine.

January 22d he was given a quarter of a grain of sulphate of morphia twice a day, which was increased to three times a day on the 26th, but was reduced to a quarter again on the 28th, as the larger dose caused pain in the stomach. By mistake the urine was not examined for sugar until six days after beginning the morphia treatment.

The iodide of potassium was omitted February 14th. The morphia was continued until after he left the hospital, was gradually diminished, and finally discontinued without difficulty and without any disagreeable results. After the urine had shown no sugar for some weeks he began to take milk, and when last seen was eating Graham bread, but had not returned to a full diet of starchy and saccharine food. He was seen at intervals for three months after leaving the hospital; the last time he said his urine had not increased above the normal amount, that his appetite was good, his food occasioned no distress; he had also gained very much in weight, was very fleshy, and had the appearance of health.

The following table will show the amount of urine voided, the per cent. of sugar, and some other items of interest:—

Date.	Amount of urine.	Remarks.
Dec. 13	6390 + cc.	7.5 per cent. sugar. Sp. gr. 1030.5
11	4205	
15	3965	
16-19	3000-3450	
20	5250	Had a bad cold. 6.25 per cent. sugar. Sp. gr. 1030.
21	6165	Iodide potassium commenced.
22	3355	
23	2890	Saponis gr. viii. three times a day.
21-26	2475-2000 +	
27	3100	Stomach disturbance. Sol. morphi. 3i. one dose.
28-31	2240-2610	
Jan. 1	5895	A cold.
2	2210	
3	2300	2.25 per cent. sugar. Sp. gr. 1026.5.
4-11	22.5-2700	
12	2000	
13	3165	Stomach disturbance.
14-16	2340-2495	
17	2045	2.77 per cent. sugar. Sp. gr. 1027.5.
18	2420	
19	2525	Sol. morphiæ. ʒss. Tr. capsici ʒiʒss.
20	2610	
21	2445	
22	3000	Pil. morphiæ gr. ʒ two times a day.
23	1575	
24	1645	
25	1440	Sulph. morphi. gr. ʒ three times a day.
26-27	1500-1695	
28	1745	No sugar. Sulph. morphia gr. ʒ three times a day.
29-1.3.81	1580-2225	
Fe. 1.8.81		No sugar on either date.
12.28.81		

The effect of disturbance of the stomach in increasing the amount of urine, and the similar effect of "taking cold," is clearly seen on several dates, the rise being from 600 cc. to 2000 cc.

It may be doubted whether the iodide of potassium was of real benefit; the urine diminished in quantity while he took it, but he was also on full diabetic diet, was confined a part of the time to bed, and had warm sponge baths. The iodide, as stated above, was given because he was a painter, and it was thought the diabetes might be due to lead poisoning; but after taking the iodide no lead was found in the urine.

Dr. Fitz has so lately published his paper on diabetic coma and acetonæmia in this Journal (February 10, 1881) that it is not necessary to refer farther to the cerebral symptoms which were manifested during the earlier days of the patient's stay in the hospital.

The benefit of the morphia treatment, commenced January 22d, was immediately apparent. It is unfortunate that no examination for sugar was made on the 23d. The only inconvenience from the morphia was the production of pain if the dose was taken too soon after eating. The patient was allowed to take it between meals at such a time as should best guard against this discomfort, and doing so no unfavorable symptoms followed. Although for several days he took one third of a grain of morphia three times a day it did not cause sleep nor give rise to unnatural drowsiness, thus illustrating the toleration of diabetic patients for that drug.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. H. RICHARDSON, M. D., SECRETARY.

MEETING of May 2, 1881.

Dr. D. H. HAYDEN read a paper on

MOVABLE KIDNEY.

which will be found on page 271 of the present number of the JOURNAL.

Dr. WEBBER said that eleven years ago he saw at the City Hospital a woman with movable kidney. The right was the one affected, and its mobility was considerable. This last winter he had been greatly puzzled by the case of a man in whom there was a tumor situated just below the liver, and so close to it that it was difficult to say whether it was a diseased kidney or a growth from the liver itself. On further examination a sulcus was found between the tumor and the liver. Though the mass could be moved its mobility was not as great as that of a movable kidney. The urine contained a large amount of blood. The patient recovered from this attack, but three weeks later he had a similar one. He then noticed that the tumor in the right side was larger than before, and somewhat tender. As before, the urine contained blood. Between these attacks of hæmaturia there was nothing abnormal in the urine, neither blood, casts, nor albumen. The man improved in flesh and strength, and went home. Dr. Webber had not been able to make up his mind whether it was a diseased kidney, or one which, from some abnormal position, was subject to periodical attacks of congestion.

Dr. MIXOT said that movable kidney is not rare.

He had seen a good many at the hospital. There was one case which was quite remarkable. The abdominal walls were so thin that the displacement of the kidney could be demonstrated with the greatest ease. A very convenient way to examine the kidney, which he had tried many times, was first to place the patient in a sitting posture on the bed, with legs out straight. Then put the thumb of the right hand behind the back under the ribs, with the other fingers in front. The tumor can thus be pressed out and made to fall into the palm of the hand and fingers in front. Some years ago he had been asked to give an opinion whether a certain case was suitable for operation. The case was that of a nervous dyspeptic woman with a fissure of the cervix uteri. On exploring the abdomen a movable tumor was found beneath the ribs of the right side. When the patient sat up it could be made to move in all directions with ease.

Another case which he had just seen was that of a woman in whom he had discovered a movable kidney two months ago. She had never had any symptoms referable to the urinary apparatus. The tumor was kidney-shaped, and was easily displaced.

DR. DRAPER thought the diagnosis of this condition of the kidney not easily mistaken, and referred to the case of a woman who found it in herself. She could displace her kidney at will, the tumor slipping downwards and forwards or out of reach. The right kidney was affected. The abdominal walls were very thin, so that the tumor could easily be perceived.

DR. GEORGE STEADMAN spoke of the case of a woman in whose abdominal cavity a movable tumor was found. Nothing had been observed till some months after the birth of her last child. After several examinations he had come to the conclusion that she had a movable kidney. There were no uncomfortable symptoms and no treatment.

DR. DRAPER reported a case of

PROLONGED INTESTINAL OBSTRUCTION,

which will be found on page 273.

DR. J. G. BLAKE spoke of the benefit derived from aspiration in cases of excessive accumulation of intestinal gases. The first patient whom he aspirated in this condition was kept alive five months, the aspirator having been used one hundred to one hundred and fifty times. He recently sent to the hospital a case of intestinal obstruction, with much flatus, which was aspirated four or five times with great relief. After two or three weeks his bowels moved naturally, but he died finally with inflammation of the parotid gland. In the case of a woman the aspirator was used with good results after a constipation of thirty-five days. By the timely use of a small aspirating needle we can relieve the distention which is the great source of danger.

DR. BOWDITCH asked whether Dr. Blake had any knowledge of the character of the obstruction in these cases, and whether it would not have been possible, in the light of modern surgery, with comparative safety to lay open the abdomen and remove the obstruction.

DR. BLAKE said in reply that a good deal depends on the history of the case. If the trouble was probably a stricture of the intestine there would be very little use in operating. In a case where there was no history of previous inflammatory action and absence of symptoms of inflammation, the physician does not do his whole duty to his patient unless he urges the advisability of exploratory incision. In the case spoken of

by him he did not think the patient had every chance given. Under similar circumstances, in the probable absence of stricture, tumor, or some cause that could not be removed, he should advise operating.

DR. BOWDITCH spoke of a case which he saw many years ago where he thought the man's life might have been saved by gastrotomy. The obstruction was caused by a band of cicatricial tissue which might easily have been cut. At that time no one thought of opening the abdominal cavity for any reason. Dr. Bowditch spoke also of a case which was supposed to be ovarian disease, and which proved to be a cyst of the broad ligament. This was relieved by tapping. A tumor then appeared on the other side, which occupied one half the space between the ribs and the groin. Fluctuation could be felt from front to back. A large amount of pus was removed by operation. Abscesses and openings appeared in the groin and thigh, which seemed to be connected with the primary trouble. Two years ago small sinuses appeared in the abdominal wall, which discharged fecal matter. It was suggested that the whole trouble might have originated in the kidney, and the advisability of removing it was considered. It was decided against the operation. Now that the patient must otherwise die, the question is whether something cannot be done by opening the abdomen.

DR. PARKS referred to the case of a friend in whom some obscure intestinal obstruction existed. So good an authority as Dr. Agnew did not hesitate to suggest operative interference should other means fail. Fortunately, relief came without resorting to abdominal section.

Recent Literature.

A Treatise on Diseases of the Joints. By RICHARD BARWELL. Second edition. New York: Wm. Wood & Co.

The publishers have done wisely in including this in the new "Library of Standard Medical Authors." It is, without doubt, the best manual on the subject in the English language, and in some respects is to be preferred to Hueter's *Klinik der Gelenkrankheiten*, a recognized German authority.

Mr. Barwell has added largely to the matter in the first edition. He still shows a commendable independence of tradition and a readiness to think for himself, which adds to the value of the book. There is also a fuller quotation of foreign authorities than is the rule in English medical literature.

The writer has, however, attempted to cover too much ground with the outlay of knowledge at his disposal, and occasional superficiality results.

In general it may be said that the portion devoted to pathology, symptoms, and the relation of cases is more satisfactory than that on treatment. The writer apparently belongs to that class of surgeons who treat tumor albus by absolute rest, "to a considerable extent" (to use newspaper slang), cod-liver oil, "steel," excision or amputation — rather than by meeting the various indications incident to the chronic course of the disease by absolute fixation, extension with limited motion, motion with protection from jar or operative interference, as may be demanded. The definite rules for excision or for expectant treatment are not stated as fully as could at present be done, and the author's acquaintance with surgical appliances appears to be

limited. On purely scientific subjects, Mr. Barwell has not done justice to the question, now an important one, of tuberculosis in fungous arthritis. In the matter of "distraction" he contents himself with quoting Reyher, but has overlooked Schüller's later experiments. The coincidence mentioned of phymosis and hip disease in one hundred cases would be of more value if a thorough consideration of the frequency of phymosis in health were added.

The loss of faradic muscular contractility in chronic disease of joints is not referred to, and it is surprising to find that mobility of a joint under chloroform (which is the rule in the early stage of real hip disease) is mentioned as an important symptom in hysterical disease of a joint.

A few "Americanisms," as they would be called if the book were written in this country, are to be found: "symptom-pain," "limb-segment," page 35. "Dr. Lewis Sayre was round the wards with me," page 288. But this latter may be figurative, and refer to a circle of good fellowship or a halo of surgical skill.

A Paper on the Relations of the Minute Blood-Vessels to the Fat Cells in the Fascia of the Calf's Neck. Illustrated by Photographs and Drawings. Read before the Richmond Microscopical Society. By WILLIAM R. WEISGER, M. D., of Manchester, Va., President of the Society.

There is, we think, no pretense on the part of the author to present anything new bearing on this subject, but rather to show the photographs that illustrate the paper. He appears to be a very conscientious worker, and well versed in technical methods. His plan of substituting picric for oxalic acid in Norris and Shakespear's method of double staining appears well worth trying. We may say incidentally that beautiful as are the results of this method we have not found them lasting. The photographs are of unequal merit. We adhere to our opinion that drawings are to be preferred, but can gladly praise many of these very highly. We have seen photographs that could not be compared to them presented with great ostentation.

T. D.

The Hunterian Oration delivered at the Royal College of Surgeons of England on the 14th of February, 1881. By LUTHER HOLDEN, Ex-President of the College of Surgeons of England, etc. Printed at the request of the President and Council. London: J. & A. Churchill. 1881.

The name of John Hunter holds a remarkable position in the history of modern English medicine. He made his power felt in so many different fields that one can as little escape from his influence in the domain of medical science as find a spot on the continent of Europe that bears no trace of the hand of Napoleon.

But if he has done much for medicine he has also suffered much from medical biographers, and only a bold man would willingly undertake to say anything new about him. To be called upon to pronounce the Hunterian Oration must be by no means an unmixed pleasure.

Every one familiar with Mr. Holden's *Landmarks* will readily understand that whatever he had to say

as Hunterian orator was gracefully said and well repaid the listener; that he should have found something new to say is not so self-evident. That he should have found records hitherto unpublished shows how universal it is to accept for truth the statements of our predecessors without an attempt to verify them.

Mr. Holden's reputation as an instructor is not confined to his own side of the Atlantic, and he naturally looks upon Hunter from a teacher's standpoint. It is as an anatomist and teacher of anatomy that Hunter is particularly interesting to him; consequently he dwells at length upon his merits as a teacher.

At the close of his oration the orator turned somewhat abruptly to the discussion of the necessity of a preliminary classical training for medical students. Though unexpressed there was doubtless present to Mr. Holden's mind the thought that Hunter, as an extreme example of a successful man with very little classical training, should not be held up as a model in the education of medical students of the present day. Mr. Holden's plea for a classical education was quoted in the *JOURNAL* soon after its delivery.

Treatment of Varicocele by Excision of Redundant Scrotum. Illustrated by new instruments and an account of fifteen successful cases. By M. H. HENRY, M. D. New York: J. H. Vail & Co. 1881, pages 24.

This is by no means a new operation, having been proposed by Sir Astley Cooper, who published five cases, and it has been occasionally repeated since. Dr. Henry believes that it offers at least as good a prospect of cure as other operations, without the dangers attending the various methods employed for the obliteration of the enlarged veins. The new instruments consist of a serotal clamp—which embraces the exact portion which it is desired to remove; its use ensures regular surface for coaptation and thus favors union by first intention—and a pair of strong sharp scissors, which the author prefers to the knife. A few of the cases have been seen after the lapse of several years and have shown good results.

Landmarks, Medical and Surgical. By LUTHER HOLDEN, assisted by JAMES SHUTER. From the Third English Edition, with Additions by WILLIAM W. KEEN, M. D. Philadelphia: Henry C. Lea's Son & Co. 1881.

The distinctive feature of this edition consists in the additions by Dr. Keen. They are not very numerous, but are well chosen, and add decidedly to the value of the work.

—A class of nurses belonging to St. Thomas's Hospital has commenced to receive instruction in the details of sick-room cookery, at the National Training School for Cookery, South Kensington, which will, no doubt, much promote the labors of the medical staff, and provide for the patients suitably prepared food to meet the necessities of the case.

—A case of chronic lead-poisoning is reported by M. Malherbe, in which the lead was contained in matches as the chromate, the matches being used to light a pipe

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 22, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

PRESIDENT GARFIELD'S DEATH.

THE intelligence received concerning President Garfield's condition since last Friday prepared the profession and the public for an early fatal termination to the prolonged struggle which has been carried on since the unhappy 2d of July when he was struck by the assassin's bullet. The severe chill of Saturday, and the successive chills of Sunday and Monday morning, cut away the last vestige of the little ground for hope upon which the sanguine have rested their beliefs, and even the despairing their wishes, and left the public confronted with little less than the certainty of what to the experienced surgeon has long been more than a probability — death.

The distinguished sufferer himself after twelve tedious weeks of pain, weariness, and uncertainty, only varied by hopes alternating with fears, weeks marked by a really heroic quietude, simplicity, and tranquillity upon the part of the patient, — he himself is at length at rest. The nation is mourning its loss, discovering, as so often happens, the value of what is taken away, and seeking a sad consolation in the belief that lessons of more value may and will be drawn by the people at large from these short but anxious months than from years full of happy and easily prosperous days.

In regard to the professional aspects of the case, no one, we believe, is in a position to say that the wound was not from the beginning of a necessarily fatal nature, or that other measures than those taken could have averted the result we all deplore. Some changes in the President's surroundings, had they been feasible, an abstract wisdom would doubtless have dictated. This much is at present permissible to say.

The result of the autopsy is already before the public, and it is probable that many histories of all the details of the case from various points of view will soon enough be published.

Neither the profession nor the public are in the mood at present for studies and discussions of this nature. There are, however, lessons which the life and closing days of President Garfield preëminently illustrate, which he who runs may read, and which we may all now lay to heart; such lessons are the power of the really strong man against "the slings and arrows of outrageous fortune," the beauty of simplicity of character with honesty of purpose, the patient, quiet endurance of unavoidable fate.

MALARIA IN NEW ENGLAND.

Our previous remarks upon the gradual reappearance of malarial diseases in various parts of New England having excited some attention, we reproduce the text of Dr. Samuel A. Green's observations upon its early existence in the neighborhood of Boston, as given in his Centennial Address before the Massachusetts Medical Society:—

"The character of the diseases that prevailed in the early days of the colony was substantially the same, though not entirely, as nowadays. It is known that intermittent fever often occurred in certain sections of Massachusetts, where now it is never seen.

"The Reverend Mr. Danforth, of Roxbury, during the winter of 1660, makes the following entry in the Church Records; 'The Lord was pleased to visit vs, with epidemical colds, coughs, agues, & fevers.' (Page 199.) Under date of September 8, 1671, he says furthermore: 'This summer many were visited with y^e ague & fever.' And again the next year, September 11, he records: 'Agues & fevers prevailed much among vs about y^e Bay, & fluxes & vomiting at Boston.' These extracts are taken from the printed edition, previously noticed.

"John Josselyn, who has been already mentioned in these pages, wrote *An Account of Two Voyages to New-England*, which was published at London in the year 1674. He speaks of arriving at Boston, September 1, 1671, and finding 'the Inhabitants exceedingly afflicted with griping of the guts, and Feaver, and Ague, and bloody-Flux.' (Page 213.) In another place he says that 'the Diseases that the *English* are afflicted with, are the same that they have in *England*, with some proper to *New-England*, griping of the belly (accompanied with Feaver and Ague) which turns to the bloody flux, a common disease in the Countrey.' (Page 183.) Joshua Scottow, in his *Old Men's Tears*, published in 1691, with a nomenclature more expressive than elegant, speaks of the 'burning and spotted Fevers, shaking Agues, dry Belly Aches, plague of the Guts, and divers other sore distempers' (page 15), which have afflicted the plantation. The plain Anglo-Saxon word, used as a synonym of the intestinal canal, has gone down in the language, and become indelicate to this generation."

Since our last issue our attention has been called to a case of undoubted tertian presenting itself in Duxbury in an individual who had never been absent from the town-ship, the diagnosis being only rendered doubtful by the fact that the case was entirely unprecedented within the memory of the attending physician.

Dr. Snow, the efficient and experienced registrar of Providence, has recently on several occasions made mention of the development of malarial affections in certain parts of that city.

We should be glad to receive for publication any carefully-observed cases of malarial taint occurring in the neighborhood of Boston or in New England at large in which the native origin of the poison is capable of proof.

THE SECRETARY-GENERAL OF THE INTERNATIONAL MEDICAL CONGRESS.

THE honor of knighthood bestowed by the Queen upon Mr. William MacCormac, the secretary-general of the late International Medical Congress, is a distinction which that gentleman certainly most fairly earned by his labors in preparing for the meeting of the Congress, and by the very marked success which characterized the arrangements made by him.

During the actual hurry, excitement, and preoccupation of such a week in London as that during which the Congress was held the eager participant is too apt to take all the facilities and conveniences which seem, as it were, to offer themselves, and which enable him to do and to see so much as matters of course. In the present instance the success of all the arrangements was so very striking that it could scarcely escape the attention of even the careless.

We are glad that the efforts of the secretary-general, to whom, with his able corps of assistants, the satisfactory results referred to were largely due, should receive this public recognition.

PROF. WM. WARREN GREENE.

WITH great regret we have to record the death of Prof. Wm. Warren Greene, of Portland, Maine, which occurred lately on board the steamer *Parthia* as he was returning from attendance upon the late International Congress at London. Professor Greene's talents and well-known skill as a surgeon earned him a very prominent professional position, especially in the State in which he lived. A more extended notice of his life and labors than the recent announcement of his decease permits this week will be given in the next issue of the JOURNAL.

Our readers will recall the very bright, entertaining, and instructive letter from Professor Greene's pen describing the proceedings of the Congress, and especially the discussions in the Surgical Section, which appeared in our columns only a few weeks since.

MEDICAL NOTES.

— Thirty or more cases of fever — some evidently typhoid, and all probably coming under that title — have occurred at Nahant. The annual increase in typhoid fever began earlier than usual this year in Boston and vicinity; the cases though numerous have been of rather a mild character. The outbreak in Nahant, however, seems to be a local epidemic. There are rumors that the sanitary conditions in some parts of the town are not as favorable as they might or should be. We should be sorry to think that any of the inhabitants would approve of the transformation of an exhausted well into a cess-pool.

— Gloucester reports a case of typhus fever, the origin of which we have not learned, but it probably is to be set down as one of the penalties paid for foreign commerce.

— As a contribution to the history of the United

States Pharmacopœia, as it is somewhat doubtful to whom the credit of originating the idea is due, the following extract from the *New England Journal of Medicine and Surgery* (Boston, July, 1821, vol. x., p. 293) may be interesting: "In the year 1808 the Massachusetts Medical Society published a Pharmacopœia. While it was in preparation circular letters were sent to the different medical institutions in the United States inviting them to coöperate in the work, and to render it national. The proposition was not acceded to, and the Pharmacopœia appeared as the work of a medical society of a single State."
